OPTIMAL COMBINATION OF DISTRIBUTED ENERGY SYSTEM
IN AN ECO-CAMPUS OF JAPAN

ABSTRACT
In this study, referring to the Distributed Energy Resources Customer Adoption Model (DER-CAM) which was developed by the Ernest Orlando Lawrence Berkeley National Laboratory (LBNL), E-GAMS programmer is developed with a research of database of energy tariffs, DER (Distributed Energy Resources) technology cost and performance characteristics, and building energy consumption in Japan. E-GAMS is a tool designed to find the optimal combination of installed equipment and an idealized operating schedule to minimize a site’s energy bills. In this research, by using E-GAMS, we present a tool to select the optimal combination of distributed energy system for an Ecological-Campus, Kitakyushu, Science and Research Park (KSRP). We discuss the effects of the combination of distributed energy technologies on the energy saving, economic efficiency and environmental benefits.

INTRODUCTION
In recent years as a supplement for regular large-scale power generation system, Distributed Energy Resources (DER) system has got more comprehensive attention. This attention is built on the vision that future electric power system will not be organized solely as centralized systems as they are today. One possible adjunct to the traditional paradigm is the microgrid (µGrid), a localized network of DER system matched to local energy demands. Under this background, DER system, such as natural power system (wind, solar) and co-generation, also known as CHP (Combined heat and power), has been developed greatly during the last 20 years.

In order to introduce DER system and improve the environment of energy system, it is necessary to have a study on choosing and designing economically optimal DER systems.

In previous research [1], Distributed Energy Resources Customer Adoption Model (DER-CAM) developed by Lawrence Berkeley National Laboratory in U.S.A has been discussed. However, it is necessary to consider the difference in climate condition and price structure between Japan and U.S.A. Therefore referring to the DER-CAM, E-GAMS programmer was developed with a research of database of energy tariffs, technology cost and performance characteristics, and building energy consumption in Japan. E-GAMS is a tool which used The General Algebraic Modeling System (GAMS) to design methods and tools for finding the optimal combination of installed equipment and an idealized operating schedule to minimize a site's energy bills.
In this research, as a sample an Ecological-Campus (Figure 1), Kitakyushu, Science and Research Park (KSRP) is selected and five cases of this pattern are utilized to find the optimal combination of installed equipment to minimize a site’s energy bills. As a description of energy system of the Ecological-Campus, new energy systems have been introduced. And the energy system not only can supply electricity, but also can recover exhaust heat by absorption chiller or heat exchanger. Figure 2 shows the image chart of energy supply in Ecological-Campus.

CONCEPT OF OPTIMIZATION

Firstly, in order to introduce DER system, regional features including demand side, electricity load and heat load, technique and investment must be comprehensively estimated. Figure 2 shows the optimal model. By
this model, requirement, market information (gas price and electricity price, etc) and technical information (co-generation, PV, etc.) could be comprehensively estimated to get a customer adoption decision of DER system.

OUTLINE OF GAMS
In generally speaking, GAMS is a high-level modeling system for mathematical programming and optimization. The actual mathematical program is modeled via user-defined algebraic equation. GAMS then compiles them and applies standard solvers to the resulting problem. The features can be mainly described as follows:
1).GAMS lets the user concentrate on modeling. By eliminating the need to think about purely technical machine-specific problems such as address calculations, storage assignments, subroutine linkage, and input-output and flow control, GAMS increases the time available for conceptualizing and running the model, and analyzing the results.
2).Using GAMS, data are entered only once in familiar list and table form. Models are described in concise algebraic statements which are easy for both humans and machines to read.

With the two features, we designed an optimal model as tool for study of DER system by GAMS

OUTLINE OF E-GAMS
Figure 3 shows the execution menu of E-GAMS.

E-GAMS is an optimization tool for DER technology selection. The following could be carried out:
1).E-GAMS minimizes the annual energy cost of a given customer, including DER investment costs, based on input data consisting of DER technology cost and performance, electricity and natural gas tariffs, and end-use energy loads such as space heating, cooling, hot water, and electricity only. E-GAMS reports the optimal technology selection and operation schedule to meet the end-use loads of the customer.
2).The primary energy consumption and carbon emissions resulting are calculated

Fig.3.E-GAMS execution menu
3). Energy sale price Yen/MJ is calculated.

**HYPOTHESIS OF OPTIMAL MODEL**

The hypotheses of selected system are shown as follows:

1). The benefit of distributed energy system is from the reducing of electricity rate and gas rate.
2). Owing to the reason of no extra of electric power, we have never considered the limit of technology on electrical power selling system
3). Total power generation only supply to Kitakyushu Science and Research Park (KSRP), not for the other consumer.
4). When demand exceeds supply it is admitted to purchase more power from Power Company.
5). Price and function of equipment are assumed according to what manufactory offer to. Moreover, setting and other cost are not considered in the basic investment.
6). At the same status of technique, the difference of capacity is not to be considered in the economy.

**CASE DESCRIPTION AND SETTING OF DATABASE**

**Case description**

In this paper, based on the present model, three cases will be discussed as follow: Case1 is Do-Nothing: No DER investments are considered. No DER investments are considered. This
scenario provides the annual energy cost, consumption, and emissions prior to DER investment.
Case 2 is DER with CHP: Using E-GAMS to get the optimal technology selection. (Optimal combination)
Case 3 is Case 2 with PV: The case must include PV (150kW * 1). Then Using E-GAMS to get the optimal technology selection.
Case 4 is Case 2 with PV and FC: This case must include PV (150kW * 1) and FC (200kW*1).
Case 5 is current system: The case use current technology selection. PV (150kW*1), FC (200kW*1), GE (160kW*1)

Electricity and Heat Load Demand
In this study, the hourly load demand of 8760 hours for electricity and heat load demand were according to data measured in 2003. Figure 2 shows the measured result of the electricity, cooling, space heating, and hot water loads. Each shows every month loads

Setting of gas price, electricity price
It is clearly that electricity price refer to Kyushu electric power company, just as shown in figure 5. Structure of electricity price is made up of basic charge, daytime unit rate, night unit rate and peak charge. Figure 6 shows the system of gas price. In generally speaking, basic charge is made up of gas basic service fee, fixed fee of gas and maximum season basic charge. (¥1 = ¥ 120)

Setting of DER Technology Information

Table 1 shows a part of the DER Technology Information for E-GAMS. It is itemized by natural gas engine (GE), gas turbine (GT), micro turbine (MT), fuel cell (FC), and photovoltaic (PV). All equipment (besides PV) can be purchased for electricity generation only, and with heat recovery for heating (HX), or with heat recovery for heating and absorption cooling (ABSHX). Data includes capacity, lifetime (in years), turnkey capital costs, maintenance costs, heat rate, and electrical efficiency.

ANALYSIS OF SIMULATION RESULT

Economic efficiency

Table 1 shows the simulation results of cases. The Do-Nothing total energy bill is $1,243,280. As an economically optimal combination, a 500kW CHP natural gas engine and a 500kW natural gas engine were selected, resulting in decreased electricity purchase and increased natural gas purchase. Total annual fuel costs (electricity and natural gas) are reduced by 56% and the total annual energy costs (including the capital and maintenance costs) are reduced by 45%. The payback period is 3.11 years.

For the case 2 and case 3 a 500kW CHP natural gas engine was chosen. Compared with the Do-Nothing case, the total annual energy bill saving are separately 41% with a payback period of 4.98 and 39% with a payback period of 6.56.

The current system installed capacity is only 505kW, but the installation cost is $190,945, resulting in the reduction is lower and payback period become 44.76 years.

Load composition

Figure 7 shows how five cases meet electricity loads. According to the figure, the compositions of Annual Electricity Generation (kWh) is more than the other compositions in case 2 (DER with CHP) and case 3 (PV+ (DER with CHP)). The composition of PV is about 2~3% in every case which uses PV. As optimal combination case (case 2) mainly use the electricity generation from the equipments which are selected by E-GAMS.
Figure 8 shows the compositions of Annual cooling load. According to the figure, when the DER+CHP is used, the cooling load is similar to Annual Cooling Load which is met by Natural Gas.

According to figure 9, the compositions of Annual Load of Space Heating which is met by CHP in Annual heat space and hot water load composition are reduced by case3→case2→case4→case5.
**Energy consumption, Carbon Emissions and Heat Unit Price**

Figure 10 shows the annual primary energy consumption in each case. The primary energy consumption of case 1 is larger than the other cases. As energy saving, case 4 (PV (150kW*1), FC (200kW*1), GE (160kW*1)) is the most environmentally optimal combination.

Furthermore, carbon emissions resulting from the five cases were analyzed (Figure 10). It is just like the figure of primary energy consumption. The Annual Off-site Carbon Emissions of case 1 is the
largest one. Carbon emissions for case 4 are reduced 27%. For the current case, carbon emissions are reduced by 16%.

The heat unit price comparisons of businesses are shown in Figure 12. According to the calculation result in Table 2, the heat unit price of case 2 (Optimal combination) is the cheapest, about 8 Yen/kWh (0.067$ kWh), and the current system (case 5) is about 16 Yen/kWh (0.067$ kWh).

CONCLUSIONS
The research used E-GAMS to simulate the five cases. And we discussed the effects of economically optimal DER in this paper. Economically optimal DER investment for each was determined, and the resulting the annual energy cost savings, fuel savings, and carbon emissions reductions are quantified. The economic and environmental effect of DER installation can be seen. Even though these studies conduct cost optimizations, fuel consumption and carbon emissions are noticeably reduced. The results of the simulation can be summarized as follows:

1) As an economically optimal combination (case 2), a 500kW CHP natural gas engine and a 500kW natural gas engine were selected. Total annual fuel costs (electricity and natural gas) are reduced by 56% and the total annual energy costs (including the capital and maintenance costs) are reduced by 45%. The payback period is 3.11 years.

2) As energy saving, case 4 is the most environmentally optimal combination. Carbon emissions are reduced 27%.

3) The heat unit price of case 2 (Optimal combination) is the cheapest, about 8 Yen/kWh.
