Stefan Rosenberger, NUKEM Nuclear Technologies

ABSTRACT

The United States Department of Energy (DOE) continually seeks safer and more cost-effective technologies for the deactivation and decommissioning (D&D) of nuclear facilities. The Deactivation and Decommissioning Focus Area (DDFA) and the DOE’s office of Science and Technology (OST) sponsors Large Scale Demonstration and Deployment Projects (LSDDPs).

The increasing number of deactivation and decommissioning (D&D) activities at nuclear facilities can generate hundreds of tons of cables per facility consuming valuable resources such as disposal space and copper. Driven by increasing environmental concerns as well as economical pressures there is a developing need for the recycling of the uncontaminated copper.

As part of the LSDDP program the NUKEM Copper Cable Recycling System (CCRS) was demonstrated November 1999 at the Idaho National Engineering and Environmental Laboratory (INEEL). This process allows recovering and recycling the uncontaminated copper contained in surface contaminated cables.

The NUKEM CCRS was originally developed in Germany for the use during the D&D of commercial power plants. Up to date the CCRS has successfully processed in Germany more than 200 metric tons of contaminated cables resulting in virtually 100% free release of copper under the German standards.

A total of 13.5 tons non and surrogate contaminated cables in a wide variety of sizes were successfully processed during the technology demonstration at INEEL. The assessment has demonstrated the mobility and flexibility of this new process.

ORIGIN OF CONTAMINATED CABLES AND THE BENEFITS FOR COPPER RECYCLING

During the maintenance, upgrade, repair, and especially the decommissioning of nuclear facilities, a wide variety of contaminated cables are generated; this cable is rubber, PVC, or polyethylene coated, varies in its diameter, and may be rigid or flexible. Usually, the cable is partially contaminated and typically, it is either

1. decontaminated for unrestricted release using labor intensive measures, or
2. packaged and shipped for contaminated disposal.

With increasing volumes to be expected in the future both of these options are costly and demand for an alternative processing method to save time and money while increasing efficiency.

Non-nuclear industries have utilized several different mechanical processes to recycle the copper from cables. However, none of these has the special constraints as they are applicable for materials processed and released from nuclear installations. An intensive engineering review of the technologies worldwide available clearly indicated that a new and innovative approach was needed to meet the nuclear safety and handling needs.
The newly developed Copper Cable Recycling Technology had the following strategic goals:

(1) Separate cable materials into contaminated/non-contaminated fractions and maintain possible cross contamination of the non-contaminated copper below free release limits.

(2) Accept all commercially used and different cable types such as rubber, PVC, or polyethylene coated. The system must be able to process cable sized ranging from telephone wire size to multi conductor power cable.

(3) Allow efficient assay of the processed materials and if possible enhance handling to prepare contaminated fractions for disposal.

(4) Consistently follow ALARA principles for safe handling and processing.

(5) Design a mobile system that can be shipped and deployed at various D&D locations.

As a result, the patented Copper Cable Recycling System (CCRS) was developed and successfully deployed at several nuclear power plant decommissioning projects in Germany. The deployment of the CCRS demonstrated the following abilities:

- Separate the feed stream into contaminated and non-contaminated end products and achieve a substantial volume reduction
- Granulate the cables into homogeneous materials for better assay
- Obtain a high purity of individual material fractions for increased value in recycling of the copper
- Provide H&S protection to the workers

In the US, DOE plans in the foreseeable future to deactivate and decommission about 5,000 facilities that have been identified as surplus. They no longer support a mission of the DOE to reduce its cost to monitor and maintain the facilities; decrease the potential for release of radioactive and hazardous materials to the environment; and decrease the risk for safety accidents due to continued deterioration of the aging facilities. Many of these facilities contain miles of insulated copper cable to supply electrical power and control systems for operation of the equipment in the facilities. These copper cables are uncontaminated or only contaminated on the external sheathing. The copper wire inside the cable is uncontaminated and is not activated unless it has been in high radiation areas.

Recovery of uncontaminated copper inside electric cables has multiple benefits. These include:

- Resale of clean copper to the scrap metal market
- Avoid the cost of disposing clean copper as low-level radioactive waste
- Avoid disposing of clean materials in disposal facilities for low-level radioactive waste (LLW) and unnecessarily depleting available space for disposal of LLW
- Avoid the need to mine virgin copper and associated environmental damage and health and safety risks to mine workers
THE COPPER CABLE RECYCLING SYSTEM DEMONSTRATION PROJECT AT INEEL

The field demonstration of the NUKEM Copper Cable Recycling Technology is part of a larger series of demonstrations executed under the Large Scale Demonstration and Deployment Project (LSDDP) funded by the Department of Energy (DOE) Office of Science and Technology (OST). The primary purpose of the LSDDP is to demonstrate innovative technologies on a large-scale basis in conjunction with Decontamination and Decommissioning (D&D) activities. The innovative technologies demonstrated are compared against DOE’s baselines and/or industrial baseline technologies in the relevant areas. The outline below describes the results of this technology demonstration that are documented in more detail in (3).

The current baseline technology used for the disposal of contaminated cables at the INEEL is to remove contaminated cable from a facility being decommissioned, size and package cables in waste storage boxes or soft-sided containers, and transport it to the Remote Waste Management Complex (RWMC) for disposal as low-level waste.

The main goal of the demonstration was to provide technical and economical benchmark information against this baseline.

Demonstration Goals and Objectives

The objective of the LSDDP is to identify existing technologies unproven in DOE D&D applications that address the defined problems or needs of DOE D&D activities. The second objective is to quantify and document the benefits that can be realized from a side by side comparison of the innovative and baseline technologies. Possible benefits include reduced cost, reduced exposure, increased safety, and ease of application and reduced schedule. This direct comparison provides an opportunity to assess the impact of the innovative technology against the baseline and validate the benefits to be gained.

The scope of this demonstration project was to demonstrate the NUKEM Copper Cable Recycling technology for processing and recycling of radioactively contaminated and non-radioactively contaminated copper cable at the Idaho National Engineering and Environmental Laboratory (INEEL) and compare it with the existing baseline technology.

The purpose of this field demonstration was to assess the effectiveness of the NUKEM Copper Cable Recycling Technology in separating uncontaminated copper from its contaminated insulation and providing separate output streams for uncontaminated copper, contaminated insulation and contaminated dust products. Subsequently the NUKEM process was evaluated in an Innovative Technology Summary Report (3) for efficiency, reliability and potential for cost and schedule savings compared to the current baseline of direct disposal at the INEEL.

Description of the Technology Demonstration

The NUKEM Copper Cable Recycling System (CCRS) was transported from Germany to the INEEL where it was setup to demonstrate the recycling of non-radioactively contaminated cable as well as cable with a surrogate contaminate applied.

The Copper Cable Recycling System is a D&D proven mobile system that is housed in two containers with the dimensions of a standard 20ft Sealand container. The system can process a wide variety of cables ranging from telephone wire with 0.5 cm or less to 6.5 cm with all available insulation materials. The typical set up time is two days or less.
The CCRS produces three distinct individually collected waste streams:

- clean copper,
- potentially contaminated insulation, and
- contaminated dust.

A total of thirteen and one-half tons of cable containing various sizes of copper conductors was available at the demonstration site for the demonstration. The total was divided into two parts to allow individual demonstrations using non-contaminated cable and demonstrations using surrogate contaminated cable. This sizing and segregating process was completed prior to receipt of the NUKEM equipment.

**System Setup and Operation**

The NUKEM Copper Cable Recycling Technology was transported via Sea and Land transport to the INEEL where it was setup to recycle non-radioactively contaminated cable as well as cable with a surrogate contaminate applied.

All activities and operations taking place during the demonstration of the surrogate contaminated wire/cable were treated as if it were radiologically contaminated including generation of appropriate documents, personal protection equipment (PPE), monitoring, environmental and air controls. All personnel associated with operations of the equipment were assumed to be radiation worker trained to the level commensurate with the radiation levels typically experienced.

Pre-job and post-job debriefings were conducted to collect observations, concerns, and opinions of operators, sampling personnel, industrial and safety personnel, and other support personnel.

The NUKEM Copper Cable Recycling Technology Operational Procedure was reviewed by all personnel involved in the setup and operation of the equipment. NUKEM personnel held a thorough review with the INEEL and Bonneville County Technology Center (BCTC) personnel and covered each step of the procedure as required during the pre-job briefings. These operational steps were followed during setup, operation and disassembly of the equipment. Personnel were briefed with the procedure and followed all safety guidelines established in the INEEL Jobs Safety Analysis (JSA).

The key components of the CCRS consist of a conveyor to feed the cable scrap into the system, a pre-shredder, and a shredder with several blades that will cut the cables into 3 to 5 mm nodules. These nodules are transported to a air separation tables that separates the insulation/dust material from the copper. Figure 1 shows the simplified process diagram.
The cables were placed on the conveyor to feed into a pre-shredder (cables can be fed as rings or as individual pieces). The larger cables were cut into approximate 1 m lengths to facilitate ease of handling and provide a constant feed into the Copper Cable Recycling System. The speed at which the cables were fed into Copper Cable Recycling Technology was determined by the amperage draw of the shredder/grinder motors. An amperage meter located on the side of the conveyor was observed continually by the operators during the process to regulate their feed rate. If the current exceeded the system limit, it was necessary to reduce or stop the feed until the amperage lowered back within the operating range.

The grinder is a horizontal shaft with grinding blades placed on the circumference of the shaft. The grinder granulates the copper wire, filler/strengthening fibers and the insulation material covering the copper wire. During the grinding process, most of the contamination is removed from the insulation due to strong mechanical sheer tension in the grinder.

The processed cable was separated into contaminated and non-contaminated material fractions in an air-separation chamber. Figure 2 shows pure copper and insulation as a result of processing. The contaminated portion is the outer covering or cable insulation and dust materials associated with the inner fillers and strength fibers used in the makeup of multi-conductor cables. The non-contaminated portion (which is the copper wire) is recovered from the inside of the insulation/covering. The relatively lighter insulation and dust granules float on a layer of air above the sieve, while the heavier copper fraction...
is separated by control of the sieve. Obtaining high volumes of uncontaminated copper for recycling and high volumes of materials that can be used as void fillers in low-level radioactive waste containers was one of the objectives of the technology demonstration.

The Copper Cable Recycling Technology processed approximately 13.5 (US) tons of insulated/coated copper cable. Data was collected during training, setup, operations, maintenance, decontamination, and demobilization activities. Granulated copper and surrogate contaminated cable insulation and dust materials were collected in 55-gallon drums or plywood waste boxes.

Large volumes of uncontaminated copper were collected, which demonstrated that contaminated insulation material can be successfully and with high purity separated from the uncontaminated copper wire so the non-contaminated copper can be recycled or reused. Data was collected for surrogate contaminated cable and non-contaminated cable using 55-gallon drums as the collection containers for the copper.

The insulation that is collected separately is a grainy, non-sticky, easily flowable material. Although experience shows that most of the insulation leaving the CCRS is uncontaminated and can be free released, the remaining contaminated fraction can easily be used to fill the void spaces of other waste boxes. Thus allowing virtually free disposal and maximization of disposal space. If the free release of insulation must be maximized as an option the cables may be wiped down prior to processing in order to remove loose surface contamination. Tests conducted in Germany have demonstrated an approximately 20% increase for the free release of insulation if wiped prior to processing. This step was naturally not performed for the demonstration.

Contaminated dust generated by the grinding process is filtered through a three-stage process to prevent the release of airborne contamination. A special design inherent to the NUKEM Copper Cable Recycling Technology prevents the rebinding of contaminated dust to the insulation material. The dust filters and the off-gas filter are encapsulated and monitored for particulate buildup and cleaned or replaced as required. The dust filters did not require replacement or cleaning during the processing of 13.5 tons of cable. Larger amounts however, would require changing the filters and this frequency would depend on the amount and types of cables being processed.

The dust was collected on standard waste boxes and is a fluffy material. Since the dust generally contains the majority of the contamination its handling should be limited. However if volumes need to be minimized it can be used as a void filler or supercompacted minimizing the volume.

The CCRS operated very well over a period of approximately five days. Twenty-one 2’x4’x8’ waste boxes containing 27,100 pounds of copper cable were processed during the demonstration. The demonstration generated 9.5 55-gallon drums of clean copper (17,250 lbs.), five 2’x4’x8’ waste boxes of granular insulation and four 2’x4’x8’ waste boxes of dust.

The unit was capable of processing up to a maximum of six tons of insulated copper cable per day, ranging from small individual strands of wire up to large (two inches in diameter) power cables, in random lengths or coils.

An average throughput during the entire demonstration was 847 lbs. per hour. This included the time required for setting up the equipment at the beginning of the day and shutting down and cleanup at the end of the day. The overall run-time for the demonstration was 32 hours.

The demonstration provided sufficient data to develop a cost benefit analysis for fair and independent comparison of the potential benefits of the NUKEM Copper Cable Recycling Technology over baseline
technologies at end-user sites. These benefits can be re-evaluated by the end-user based on the changing value of copper and changing costs of alternative disposal methods.

**Economical benchmark**

Based on the data collected during the demonstration, it is estimated that the innovative CCRS can save $350,000 if processing 50 ton of cables designated for the INEEL Remote Waste Management Complex (RWMC) landfill for disposal (see Figure 3) (3). Influenced by the cable sizes generally such a quantity could be processed in less than 15 single shift processing days. With increasing project size these cost savings will significantly increase over the baseline.

![Figure 3: Job Cost as a Function of Job Size (3)](image)

Large decommissioning projects of commercial power plants and DOE facility decommissioning will generate several hundred tons of contaminated cables. The benefits in cost savings received will be significant over the baseline technology of direct disposal. For such projects the handling, packaging, transportation and disposal costs can be significantly reduced using the NUKEM CCRS and could even upset other necessary D&D costs.

**Issues discovered and lessons learned during the demonstration**

Each time the CCRS is shut down and restarted, approximately 2 hours are required to balance the air movers at the beginning of the day and to allow the copper to clean out of the system at the end of the day. This time may vary but needs to be considered each time the CCRS is started and stopped. The CCRS is more cost effective if it can run continuously for as long as possible to avoid the startup and shutdown procedures associated with balancing the air movers and removing the remaining copper from the system. Double shifts or around the clock operation will allow even more cost-effective operation than demonstrated and documented in the economical baseline.

A large portion of the CCRS costs are mobilization and demobilization, which remain relatively the same irrespective of the quantity of cable processed. Consequently, the CCRS compares differently with the baseline technology for different size jobs. For jobs that are larger than 25,000 lbs. of cable, the CCRS will be more cost effective than the baseline technology at INEEL.
CCRS PROCESS EXPERIENCE GAINED DURING D&D PROJECTS IN GERMANY

During several D&D projects performed in Germany, the CCRS successfully separated the contaminated insulation/dust from the clean copper in the cable. The system has processed cables that were collected during the decommissioning of a fuel manufacturing plant (primarily alpha contaminated) as well as from the decommissioning of commercial power plants (primarily gamma contaminated).

Thus far, the CCRS has successfully processed more than 100 metric tons of various sized contaminated cables, as well as 100 metric tons of alpha-contaminated cables at a fuel fabrication plant.

Use of the CCRS in German commercial power plants resulted in the unrestricted release by German standards of 100% copper and 65% insulation. A total of 74% of the initial cable scrap was free released. A total of 8% of the insulation was disposed at a regular landfill utilizing the unrestricted release limits. Only 18% of the scrap cables processed (insulation and dust) were handled as contaminated waste. Figure 4 summarizes the results for such processing.

This separation of contaminated materials resulted in significant cost savings to the project (5). The copper with a high purity was free released and subsequently recycled and sold to a melter of electrolytic copper. The cost savings due to reduced disposal costs and revenue from this sale of copper contributes positively to the reduction of decommissioning costs for any nuclear facility.

DOES RECYCLING HAVE A FUTURE?

The worldwide increasing number of nuclear facilities that reach the end of their 40 year design life will generate increasing and high volumes of waste associated with their decommissioning.

The unconditional disposal of these wastes without considering the currently available technologies to minimize and recycle will rapidly deplete the disposal volumes available and will result in increased decommissioning costs.
The CCRS demonstration project has demonstrated that there are already cost savings producing solutions available that are not only supporting tight budgets but also recycle valuable materials for reuse in the industrial materials cycle. The CCRS has its immediate application at DOE sites where facility D&D is planned or underway.

The mobile system is able to support relatively small and large copper recycling projects as the demand develops on the individual sites thus eliminating extra handling, storage, container and transportation costs.

The CCRS has demonstrated the potential to significantly reduce costs for many D&D projects throughout the United States.
