Teuchos::RefCountPtr Beginner’s Guide

An Introduction to the Trilinos Smart Reference-Counted Pointer Class for (Almost) Automatic Dynamic Memory Management in C++

Roscoe A. Bartlett
Optimization and Uncertainty Estimation
Sandia National Laboratories, Albuquerque NM 87185 USA,

Abstract

Dynamic memory management in C++ is one of the most common areas of difficulty and errors for amateur and expert C++ developers alike. The improper use of operator new and operator delete is arguably the most common cause of incorrect program behavior and segmentation faults in C++ programs. Here we introduce a templated concrete C++ class Teuchos::RefCountPtr<>, which is part of the Trilinos tools package Teuchos, that combines the concepts of smart pointers and reference counting to build a low-overhead but effective tool for simplifying dynamic memory management in C++. We discuss why the use of raw pointers for memory management, managed through explicit calls to operator new and operator delete, is so difficult to accomplish without making mistakes and how programs that use raw pointers for memory management can easily be modified to use RefCountPtr<>. In addition, explicit calls to operator delete is fragile and results in memory leaks in the presents of C++ exceptions. In its most basic usage, RefCountPtr<> automatically determines when operator delete should be called to free an object allocated with operator new and is not fragile in the presents of exceptions. The class also supports more sophisticated use cases as well. This document describes just the most basic usage of RefCountPtr<> to allow developers to get started using it right away. However, more detailed information on the design and advanced features of RefCountPtr<> is provided by the companion document “Teuchos::RefCountPtr : The Trilinos Smart Reference-Counted Pointer Class for (Almost) Automatic Dynamic Memory Management in C++” [2].

Beginner’s Guide

An Introduction to the Trilinos Smart Reference-Counted Pointer Class for
(Almost) Automatic Dynamic Memory Management in C++

1 Introduction

The main purpose of this document is to provide a quick-start guide on how to incorporate the reference-counting smart pointer class Teuchos::RefCountPtr<> into C++ programs that use dynamic memory allocation and object orientation. This code is included in the Trilinos [4] tools package Teuchos. The design of Teuchos::RefCountPtr<> is based partly on the interface for std::auto_ptr<> and Items 28 and 29 in “More Effective C++” [6]. In short, RefCountPtr<> allows one client to dynamically create an object (using operator new for instance), pass the object around to other clients that need to access the object and never require any client to explicitly call operator delete. The object will (almost magically) be deleted when all of the clients remove their references to the object. In principle, this is very similar to the type of garbage collection that is in languages like Perl and Java. There are some pathological cases (such as the classic problem of circular references, see [6, Item 29, page 212]) where RefCountPtr<> will result in a memory leak, but these situations can be avoided through the careful use of RefCountPtr<>. However, realizing the potential of hands-off garbage collection with RefCountPtr<> requires following some rules. These rules are partially spelled out in the form of commandments in Appendix C.

Note that direct calls to operator delete are discouraged in modern C++ programs that are designed to be robust in the presence of C++ exception handing. This is because the raw use of operator delete often results in memory leaks when exceptions are thrown. For example, in the code fragment:

```cpp
void someFunction() {  
  A *a = new A;  
  a->f();  
  delete a;  
}
```

if an exception is thrown in the function call a->f() then the statement delete a will never be
executed and a memory leak will have been created. The class `std::auto_ptr<>` was added to the standard C++ library (see [6, Items 9 and 10]) to protect against these types of memory leaks. For example, the rewritten function:

```cpp
void someFunction() {
    std::auto_ptr<A> a(new A);
    a->f();
}
```

is robust in the event of exceptions and no memory leak will occur. However, `std::auto_ptr<>` can not be used to share a resource between two or more clients and therefore is not an answer to the issue of general garbage collection. The class `RefCountPtr<>` not only is robust in the event of exceptions but also implements reference counting and is therefore more general (but admittedly more complex and expensive) than `std::auto_ptr<>`.

The use of `RefCountPtr<>` is critically important in the development and maintenance of large complex object-oriented programs composed of many separately-developed pieces (such as Trilinos). This discussion assumes that the reader has a basic familiarity and some programming experience with C++ and has at least been exposed to the basic concepts of object-oriented programming (good sources include [3] and [7]). Furthermore, the reader should be comfortable with the use of C++ pointers and references.

The appendices contain basic reference material for `RefCountPtr<>`. In many respects, the appendices are the most important contribution of this document. For those readers that like to see the C++ declarations right away, Appendix A contains the C++ declarations for the template class `RefCountPtr<>` and some important associated non-member templated functions. Appendix B is a short reference-card-like quick-start for the use of `RefCountPtr<>`. The quick-start in this appendix shows how to create `RefCountPtr<>` objects from raw C++ pointers, how to represent different forms on constantness, cast from one pointer type to another, access the underlying reference-counted object as well as to associate and manage extra data. Appendix C gives some commandments for the use of `RefCountPtr<>` and reinforces the material in Appendix B. Appendix D gives tables of recommended idioms for how to pass raw C++ objects and `RefCountPtr<>`-wrapped objects to and from functions. More detailed discussions of all of the material in the appendices is contained in the design document for `RefCountPtr<>` [2]. Appendix E gives a listing for an example program that uses raw pointer variables and direct calls to operator `new` and operator `delete` while Appendix F shows a refactoring of this example program to use `RefCountPtr<>`.

**Note!** Anxious readers are encouraged to jump directly to Appendix E and F to get an idea of what `RefCountPtr<>` is all about. This example, together with the reference material in the appendices, should be enough for semi-experienced C++ developers to start using `RefCountPtr<>` right away.

For less anxious readers, in the following section, we describe why the use of raw C++ pointers and raw calls to operator `new` and especially operator `delete` is difficult to program correctly in even
moderately complex C++ programs. We then discuss the different ways C++ pointers are used in such programs and describe how to refactor these programs to replace some of the raw C++ pointers and raw calls to operator delete with RefCountPtr<>. In the following discussion we will define persisting and non-persisting associations and will make a distinction between them (see page 11). RefCountPtr<> is recommended for use only with persisting associations. The consistent use of RefCountPtr<> extends the vocabulary of C++ in helping to distinguish between these two types of relationships. In addition, RefCountPtr<> is designed for the memory management of individual objects, not raw C++ arrays of objects. Array allocation and deallocation should be performed using standard C++ containers such as std::vector<>, std::valarray<> or some other such convenient C++ array class. However, it is quite common to dynamically allocate arrays of RefCountPtr<> objects and use RefCountPtr<> to manage the lifetime of such array class objects.

2 An example C++ program

The use of object-oriented (OO) programming in C++ is the major motivation for the development of RefCountPtr<>. OO programs are characterized by the use of abstract classes (i.e. interfaces) and concrete subclasses (i.e. implementations). In OO programs it is common that the selection of which concrete subclass(es) to use is not known until runtime. The “Abstract Factory” [3] is a popular design pattern that allows the flexible runtime selection of what concrete subclasses to create.

Below we describe a fictitious program that demonstrates some of the typical features of an OO program that uses dynamic memory management in C++. In this simple program, handling memory management using raw C++ pointers and calls to operator new and operator delete will appear fairly easy but larger more realistic OO programs are much more complicated and it is definitely not easy to do memory management without some help.

2.1 Example C++ program using raw dynamic memory management

One of the predominate features of this example program is the use of the following abstract interface base class UtilityBase that defines an interface to provide some useful capability.

```
class UtilityBase {  
   public:  
      virtual void f() const = 0;  
};
```

In our example program, UtilityBase will have two subclasses where one or the other will be used at runtime.
In this example program the above implementation functions just print to standard out.

Some of the clients in this program have to create `UtilityBase` objects without knowing exactly what concrete subclasses are being used. This is accomplished through the use of the “Abstract Factory” design pattern [3]. For `UtilityBase`, the abstract factory looks like

```cpp
class UtilityBaseFactory {
public:
    virtual UtilityBase* createUtility() const = 0;
};
```

and has the following factory subclasses for creating `UtilityA` and `UtilityB` objects.

```cpp
class UtilityAFactory : public UtilityBaseFactory {
public:
    UtilityBase* createUtility() const { return new UtilityA(); }
};
class UtilityBFactory : public UtilityBaseFactory {
public:
    UtilityBase* createUtility() const { return new UtilityB(); }
};
```

Now let’s assume that our example program has the following client classes.

```cpp
// Simple client with no state
class ClientA {
public:
    void f( const UtilityBase &utility ) const { utility.f(); }
};

// Client that maintains a pointer to a Utility object
class ClientB {
```
UtilityBase *utility_;
public:
ClientB() : utility_(0) {}
~ClientB() { delete utility_; }
void initialize( UtilityBase *utility ) { utility_ = utility; }
void g( const ClientA &a ) { a.f(*utility_); }
};

// Client that maintains pointers to UtilityFactory and Utility objects
class ClientC {
const UtilityBaseFactory *utilityFactory_;
UtilityBase *utility_;
bool shareUtility_;
public:
ClientC( const UtilityBaseFactory *utilityFactory, bool shareUtility )
:utilityFactory_(utilityFactory)
,utility_(utilityFactory->createUtility())
,shareUtility_(shareUtility) {}
~ClientC() { delete utilityFactory_; delete utility_; }
void h( ClientB *b ) {
if( shareUtility_ ) b->initialize(utility_);
else
b->initialize(utilityFactory_->createUtility());
}
};

The type of logic used in ClientC for determining when new objects should be created or when objects should be reused and passed around is common in larger more complicated OO programs.

The above client classes demonstrate two different types of associations between objects: non-persisting and persisting.

Non-Persisting associations exist only within a single function call and do not extend after the function has finished executing. For example, objects of type ClientA and UtilityBase have a non-persisting relationship through the function ClientA::f(const UtilityBase &utility). Likewise, objects of type ClientB and ClientA have a non-persisting association through the function ClientB::g( const ClientA &a ).

Persisting associations are where a relationship between two objects exists past a single function call. The most typical kind of persisting association in an OO C++ program is where one object maintains a private pointer data member to another object. For example, persisting associations exist between a ClientC object, a UtilityBaseFactory and a UtilityBase object through the the private C++ pointer data members ClientC::utilityFactory_ and ClientC::utility_ respectively. Likewise, a persisting association exists between a ClientB object and a UtilityBase object through the private pointer data member ClientB::utility_.

Persisting relationships are significantly more complex than non-persisting relationships since
a persisting relationship usually implies that some objects must be responsible for the lifetime of other objects. This is never the case in a non-persisting relationship as defined above.

Appendix E shows an example program that uses all of the C++ classes described above. The program in Appendix E has several memory management problems. An astute reader will notice that the UtilityBaseFactory created in main() gets deleted twice; once in the destructor for the ClientC object c and again at the end of main() in an explicit call to operator delete. This problem could be fixed in this program by arbitrating “ownership” of the UtilityBaseFactory object to either main() or the ClientC object, but not both which is the case in Appendix E.

A more difficult memory management problem to catch and fix occurs in the ClientB and ClientC objects regrading a shared UtilityBase object. When shareUtility is set to false (by the user in the commandline arguments) the objects b1, b2 and c each own a pointer to different UtilityBase objects and the software will correctly delete each dynamically allocated object using one and only one call to operator delete (in the destructors of these classes). However, when shareUtility is set to true the objects b1, b2 and c will contain pointers to the same UtilityBase object and operator delete will be called on this shared UtilityBase object multiple times when b1, b2 and c are destroyed. In this case, it is not so easy to arbitrate ownership of the shared UtilityBase object to the ClientB or the ClientC objects. Logic could be developed in this simple program to insure that ownership was assigned properly but such logic would enlarge the program, complicate maintenance, and would ultimately make the software components less reusable. In more complex programs, trying to dynamically arbitrate ownership at run time is much more difficult and error prone if done manually.

### 2.2 Refactored example C++ program using RefCountPtr<>

Now we describe how RefCountPtr<> can be used to greatly simplify dynamic memory management in these types of OO programs. Appendix F shows the refactoring of the program in Appendix E to use RefCountPtr<> for all persisting relationships. In general, refactoring software that uses raw C++ pointers to use RefCountPtr<> is as simple as replacing the type T* with RefCountPtr<T>, where T is nearly any class or built-in data type.

The first persisting relationship for which RefCountPtr<> is used is the relationship between a UtilityBaseFactory object and a client that uses it. The refactoring changes the return type of UtilityBaseFactory::createUtility() from a raw UtilityBase* pointer to a RefCountPtr<UtilityBase> object. The new “Abstract Factory” class declarations (assuming that the symbols from the Teuchos namespace are in scope so that explicit Teuchos:: qualification is not necessary) become

```cpp
class UtilityBaseFactory {
public:
    virtual RefCountPtr<UtilityBase> createUtility() const = 0;
```
class UtilityAFactory : public UtilityBaseFactory {
public:
    RefCountPtr<UtilityBase> createUtility() const { return rcp(new UtilityA()); }
};

class UtilityBFactory : public UtilityBaseFactory {
public:
    RefCountPtr<UtilityBase> createUtility() const { return rcp(new UtilityB()); }
};

In addition to the change of the return type, the refactoring also requires that calls to operator new be wrapped in calls to the templated function Teuchos::rcp(...).

The refactoring shown in Appendix F does not impact the definition of the class ClientA since this class does not have any persisting relationships with any other objects. However, the definitions of the classes ClientB and ClientC do change and become

class ClientB {
    RefCountPtr<UtilityBase> utility_;  
public:
    void initialize(const RefCountPtr<UtilityBase> &utility) { utility_=utility; }  
    void g( const ClientA &a ) { a.f(*utility_); } 
};

class ClientC {
    RefCountPtr<UtilityBaseFactory> utilityFactory_;  
    RefCountPtr<UtilityBase> utility_;  
    bool shareUtility_; 
public:
    ClientC( const RefCountPtr<UtilityBaseFactory> &utilityFactory, bool shareUtility ) :utilityFactory_(utilityFactory) 
        ,utility_(utilityFactory->createUtility()) 
        ,shareUtility_(shareUtility) {} 
    void h( ClientB *b ) {
        if( shareUtility_ ) b->initialize(utility_); 
        else b->initialize(utilityFactory_->createUtility()); 
    }  
};

The first thing that one should notice about the refactored ClientB and ClientC classes is that their destructors are gone. It turns out that the compiler-generated destructors do exactly the correct thing (i.e. call the destructor on the RefCountPtr<> data members which in turns calls operator delete on the underlying reference-counted object when the reference count goes to zero).
second thing that one should notice is that the old default constructor ClientB::ClientB() which initialized the raw C++ pointer utility to null is no longer needed since RefCountPtr<> has a default constructor that does that. A third thing to notice about these refactored client classes is that the RefCountPtr<> objects are passed by const reference (see Appendix D) and not by value as the corresponding raw pointers where in the original unfactored classes. Passing RefCountPtr<> objects by const reference yields slightly more efficient code and simplifies stepping through the code in a debugger. For example, a function declared as

```cpp
void someFunction( RefCountPtr<A> a );
```

will always result in the copy constructor for RefCountPtr<> being called (and therefore stepped into in a debugger) while this same function declared as:

```cpp
void someFunction( const RefCountPtr<A> &a );
```

will often not require the copy constructor be called (except in cases where an implicit conversion is being performed as described in Appendix B) and thereby easing debugging.

As an aside, note that Appendix D gives recommended idioms for how to pass raw C++ objects and RefCountPtr<>-wrapped objects to and from functions in a way that result in function prototypes becoming as self documenting as possible, help to avoid coding errors and increase the readability of C++ code. Also, in addition to the benefit that RefCountPtr<> eases dynamic memory management, the selective use of RefCountPtr<> and raw C++ object references extends the vocabulary of the C++ language by helping to distinguish between persisting and non-persisting associations. For example, when a one sees a function prototype where an object is passed through a RefCountPtr<> such as

```cpp
class SomeClass {
public:
  void someFunction( const RefCountPtr<A> &a );
};
```

one can automatically deduce that “memory” of the A object will be retained (through a private RefCountPtr<A> data member in SomeClass no doubt) and that should automatically alter how the developer plans on calling that function and passing the A object. The refactored C++ program in Appendix F provides an example of how the idioms presented in Appendix D are put to use.

### 3 Additional and advanced features of `RefCountPtr<>`

The use cases for RefCountPtr<> described above comprise a large majority of the relevant use cases in most programs, but there there are some other use cases that require additional and more
advanced features. Some of these additional features (the C++ declarations for which are shown in Appendix A) are mentioned below:

1. **Casting**
   
   `RefCountPtr<>` objects can be casted in a manner similar to casting raw C++ pointers and the same types of conversion rules apply. Analogs of the built-in casts `static_cast<>`, `const_cast<>` and `dynamic_cast<>` are supported by the non-member templated functions `rcp_static_cast<>`, `rcp_const_cast<>` and `rcp_dynamic_cast<>` respectively. See Appendix B for examples of how they are used.

2. **Reference-count information**
   
   The function `RefCountPtr<>::count()` returns the number of `RefCountPtr<>` objects that point to the underlying reference-counted object. This information can be useful in some cases.

3. **Associating extra data with a reference-counted object**
   
   There are some more difficult use cases where certain types of information or other objects must be bundled with a reference-counted object and must not be deleted until the reference-counted object is deleted. The non-member templated functions `set_extra_data<>(...)` and `get_extra_data<>(...)` serve this purpose (see item (5) in Appendix B).

4. **Customized deallocation policies**
   
   The default behavior of `RefCountPtr<>` is to call operator `delete` on reference-counted objects once the reference count goes to zero. While this is the most commonly needed behavior, there are use cases where more specialized dellocation polices are required. For these cases, there is an overloaded form of the templated function `Teuchos::rcp(...)` that takes a templated deallocation policy object that defines how a reference-counted object is deallocated when required.

These features are discussed in detail in the design document [2].

### 4 Summary

The templated C++ class `RefCountPtr<>` provides a low-overhead option for (almost) automatic memory management in C++. This class has been developed and refined over many years and has been instrumental in improving the quality of software projects that use it consistently (for example see MOOCHO [1]). Careful use of `RefCountPtr<>` eliminates the need to manually call operator `delete` when dynamically allocated objects are no longer needed. Furthermore, it helps to reduce the amount of code that developers have to write. For example, most classes that use `RefCountPtr<>` for dynamically allocated memory do not need developer-supplied destructors. This because
the compiler-generated destructors do the exactly correct thing which is to call destructors on an object’s constituent data members. This was demonstrated in the difference between the original and refactored classes \texttt{ClientB} and \texttt{ClientC} described in Sections 2.1 and 2.2.

The class \texttt{RefCountPtr<>} also has advanced features not found in other smart-pointer implementations such as the ability to attach extra data and the customization of the deallocation policy.

B RefCountPtr<> quick-start and reference

This appendix presents a short, but fairly comprehensive, quick-start for the use of RefCountPtr<>. The use cases described here should cover the overwhelming majority of the use instances of RefCountPtr<> in a typical program.

The following class hierarchy will be used in the C++ examples given below.

class A { public: virtual ~A(){} A& operator=(const A&){} virtual void f(){} };  
class B1 : virtual public A {};  
class B2 : virtual public A {};  
class C : virtual public B1, virtual public B2 {};  
class D {};  
class E : public D {};

All of the following code examples used in this appendix are assumed to be in the namespace Teuchos or have appropriate using Teuchos::... declarations. This removes the need to explicitly use Teuchos:: to qualify classes, functions and other declarations from the Teuchos namespace.

1. Creation of RefCountPtr<> objects

(a) Creating a RefCountPtr<> object using new

RefCountPtr<C> c_ptr = rcp(new C);

(b) Initializing a RefCountPtr<> object to NULL

RefCountPtr<C> c_ptr;

or

RefCountPtr<C> c_ptr = null;

(c) Initializing a RefCountPtr<> object to an object not allocated with new

C c;
RefCountPtr<C> c_ptr = rcp(&c, false);

(d) Representing constantness and non-constantness

i. Non-constant pointer to non-constant object

RefCountPtr<C> c_ptr;

ii. Constant pointer to non-constant object

const RefCountPtr<C> c_ptr;

iii. Non-Constant pointer to constant object

RefCountPtr<const C> c_ptr;
iv. Constant pointer to constant object
const RefCountPtr<const C> c_ptr;

(c) Copy constructor (implicit casting)
RefCountPtr<C> c_ptr = rcp(new C); // No cast
RefCountPtr<A> a_ptr = c_ptr; // Cast to base class
RefCountPtr<const A> ca_ptr = a_ptr; // Cast from non-const to const

2. Reinitialization of RefCountPtr<> objects (using assignment operator)

(a) Resetting from a raw pointer
RefCountPtr<A> a_ptr;
a_ptr = rcp(new C());

(b) Resetting to null
RefCountPtr<A> a_ptr = rcp(new C());
a_ptr = null; // The C object will be deleted here

(c) Assigning from a RefCountPtr<> object
RefCountPtr<A> a_ptr1;
RefCountPtr<A> a_ptr2 = rcp(new C());
a_ptr1 = a_ptr2; // Now a_ptr1 and a_ptr2 point to same C object

3. Accessing the reference-counted object

(a) Access to object reference (runtime checked)
C &c_ref = *c_ptr;

(b) Access to object pointer (unchecked, may return NULL)
C *c_rptr = c_ptr.get();

(c) Access to object pointer (runtime checked, will not return NULL)
C *c_rptr = &c_ptr;

(d) Access of object’s member (runtime checked)
c_ptr->f();

4. Casting

(a) Implicit casting (see copy constructor above)

(b) Casting away const
RefCountPtr<const A> ca_ptr = rcp(new C);
RefCountPtr<A> a_ptr = rcp_const_cast<A>(ca_ptr); // cast away const!

(c) Static cast (no runtime check)
RefCountPtr<D> d_ptr = rcp(new E);
RefCountPtr<E> e_ptr = rcp_static_cast<E>(d_ptr); // Unchecked, unsafe?
(d) **Dynamic cast (runtime checked)**

```cpp
RefCountPtr<A> a_ptr = rcp(new C);
RefCountPtr<B1> b1_ptr = rcp_dynamic_cast<B1>(a_ptr); // Checked, safe!
RefCountPtr<B2> b2_ptr = rcp_dynamic_cast<B2>(b1_ptr); // Checked, safe!
RefCountPtr<C> c_ptr = rcp_dynamic_cast<C>(b2_ptr); // Checked, safe!
```

5. **Managing extra data**

   (a) **Adding extra data**
   ```cpp
   set_extra_data(rcp(new B1),"A:B1",&a_ptr);
   ```

   (b) **Retrieving extra data**
   ```cpp
   get_extra_data<RefCountPtr<B1>>(a_ptr,"A:B1")->f();
   ```

   (c) **Resetting extra data**
   ```cpp
   get_extra_data<RefCountPtr<B1>>(a_ptr,"A:B1") = rcp(new C);
   ```
Commandments for the use of `RefCountPtr<>`

Here are listed commandments for the use of `RefCountPtr<>`. These commandments reinforce some of the material in the quick-start in Appendix B. The reasoning behind these commandments can be found in the design document for `RefCountPtr<>` [2]. Along with each commandment is one or more anti-commandments stating the negative of the commandment. C++ code fragments are also included to demonstrate each commandment and anti-commandment.

**Commandment 1** Thou shall put a pointer for an object allocated with operator new into a `RefCountPtr<>` object only once. The best way to insure this is to call operator new directly in a call to `rcp(...)` to create a dynamically allocated object that is to be managed by a `RefCountPtr<>` object (see item (1a) in Appendix B).

**Anti-Commandment 1** Thou shall never give a raw C++ pointer returned from operator new to more than one `RefCountPtr<>` object.

Example:

```cpp
A *ra_ptr = new C;
RefCountPtr<A> a_ptr1 = rcp(ra_ptr); // Okay
RefCountPtr<A> a_ptr2 = rcp(ra_ptr); // no, No, NO !!!!
```

**Anti-Commandment 2** Thou shall never give a raw C++ pointer to an array of objects returned from operator new[] to a `RefCountPtr<>` object.

Example:

```cpp
RefCountPtr<std::vector<C> > c_array_ptr1 = rcp(new std::vector<C>(N)); // Okay
RefCountPtr<C> c_array_ptr2 = rcp(new C[N]); // no, No, NO !!!!
```

**Commandment 2** Thou shall only create a NULL `RefCountPtr<>` object by using the default constructor or by using the `null` enum (and its associated special constructor) (see item (1b) in Appendix B). Trying to assign to NULL or 0 will not compile.

**Anti-Commandment 3** Thou shall not create a NULL `RefCountPtr<>` object using the templated function `rcp(...)` since it is very verbose and complicates maintenance.

Example:
RefCountPtr<A> a_ptr1 = null;  // Yes :-)  
RefCountPtr<A> a_ptr2 = rcp<A>(NULL);  // No, too verbose :-(

**Commandment 3** Thou shall only pass a raw pointer for an object that is **not** allocated by operator **new** (e.g. allocated on the stack) into a RefCountPtr<> object by using the templated function rcp<T>(T* p, bool owns_mem) and setting owns_mem to false (see item (1c) in Appendix B).

**Anti-Commandment 4** Thou shall never pass a pointer for an object **not** allocated with operator **new** into a RefCountPtr<> object without setting owns_mem to **false**.

Example:

```cpp
C c;
RefCountPtr<A> a_ptr1 = rcp(&c,false);  // Yes :-)
RefCountPtr<A> a_ptr2 = rcp(&c);       // no, No, NO !!!!
```

**Commandment 4** Thou shall only cast between RefCountPtr<> objects using the default copy constructor (for implicit conversions) and the nonmember template functions rcp_static_cast<>(- ...), rcp_const_cast<>(...) and rcp_dynamic_cast<>(...) (see item (4) in Appendix B).

**Anti-Commandment 5** Thou shall never convert between RefCountPtr<> objects using raw pointer access.

Example:

```cpp
RefCountPtr<A> a_ptr  = rcp(new C);
RefCountPtr<B1> bl_ptr1 = rcp_dynamic_cast<B1>(a_ptr);  // Yes :-)
RefCountPtr<B1> bl_ptr2 = rcp(dynamic_cast<B1*>(a_ptr.get()));  // no, No, NO !!!!
```
D Recommendations for passing objects to and from C++ functions

Below are recommended idioms for passing required\(^1\) and optional\(^2\) arguments into and out of C++ functions for various use cases and different types of objects. These idioms show how to write function arguments prototypes which exploit the C++ language in a way that makes these function prototypes as self documenting as possible, avoid coding errors and increase readability of C++ code. In general, `RefCountPtr<>` objects should be passed and manipulated as though they were raw C++ pointers. The main difference is that while raw C++ pointer objects should generally be passed by value, `RefCountPtr<>` objects should generally be passed by reference for several reasons (see [2] for more details).

<table>
<thead>
<tr>
<th>Argument purpose</th>
<th>Non-Persisting</th>
<th>Persisting</th>
</tr>
</thead>
<tbody>
<tr>
<td>non-mutable object (required(^1))</td>
<td><code>S s</code> or <code>const S s</code> or <code>const S &amp;s</code></td>
<td><code>const RefCountPtr&lt;const S&gt; &amp;s</code></td>
</tr>
<tr>
<td>non-mutable object (optional(^2))</td>
<td><code>const S *s</code> or <code>const RefCountPtr&lt; const S &gt; &amp;s</code></td>
<td><code>const RefCountPtr&lt; S &gt; &amp;s</code></td>
</tr>
<tr>
<td>mutable object</td>
<td><code>S *s</code></td>
<td><code>RefCountPtr&lt; S &gt; &amp;s</code></td>
</tr>
<tr>
<td>array of non-mutable objects</td>
<td><code>const S s[]</code> or <code>const RefCountPtr&lt; const S &gt; s[]</code></td>
<td><code>const RefCountPtr&lt; S &gt; s[]</code></td>
</tr>
<tr>
<td>array of mutable objects</td>
<td><code>S s[]</code></td>
<td><code>const RefCountPtr&lt; S &gt; s[]</code></td>
</tr>
</tbody>
</table>

C++ declarations for passing small concrete (i.e. with value semantics) objects to and from functions where `S` is a place holder for an actual built-in or user-defined data type.

<table>
<thead>
<tr>
<th>Argument purpose</th>
<th>Non-Persisting</th>
<th>Persisting</th>
</tr>
</thead>
<tbody>
<tr>
<td>non-mutable object (required(^1))</td>
<td><code>const A &amp;a</code></td>
<td><code>const RefCountPtr&lt; const A &gt; &amp;a</code></td>
</tr>
<tr>
<td>non-mutable object (optional(^2))</td>
<td><code>const A *a</code></td>
<td><code>const RefCountPtr&lt; const A &gt; &amp;a</code></td>
</tr>
<tr>
<td>mutable object</td>
<td><code>A *a</code></td>
<td><code>const RefCountPtr&lt; A &gt; &amp;a</code></td>
</tr>
<tr>
<td>array of non-mutable objects</td>
<td><code>const A* a[]</code> or <code>const RefCountPtr&lt; const A &gt; a[]</code></td>
<td><code>const RefCountPtr&lt; A &gt; a[]</code></td>
</tr>
<tr>
<td>array of mutable objects</td>
<td><code>A* a[]</code></td>
<td><code>const RefCountPtr&lt; A &gt; a[]</code></td>
</tr>
</tbody>
</table>

C++ declarations for passing abstract (i.e. with reference or pointer semantics) or large concrete objects to and from functions where `A` is a place holder for an actual abstract C++ base class.

\(^1\) Required arguments must be bound to valid objects (i.e. can not be null)
\(^2\) Optional arguments may be NULL in some cases

27
E  Listing: Example C++ program using raw dynamic memory management

```cpp
#include "example_get_args.hpp"

// Abstract interfaces
class UtilityBase {
public:
    virtual void f() const = 0;
};
class UtilityBaseFactory {
public:
    virtual UtilityBase* createUtility() const = 0;
};

// Concrete implementations
class UtilityA : public UtilityBase {
public:
    void f() const { std::cout" UtilityA::f() called, this="<<this<<"\n"; }
};
class UtilityB : public UtilityBase {
public:
    void f() const { std::cout" UtilityB::f() called, this="<<this<<"\n"; }
};
class UtilityAFactory : public UtilityBaseFactory {
public:
    UtilityBase* createUtility() const { return new UtilityA(); }
};
class UtilityBFactory : public UtilityBaseFactory {
public:
    UtilityBase* createUtility() const { return new UtilityB(); }
};

// Client classes
class ClientA {
public:
    void f( const UtilityBase &utility ) const { utility.f(); }
};
class ClientB {
    UtilityBase *utility_;
public:
    ~ClientB() { delete utility_; }
    void initialize( UtilityBase *utility ) { utility_ = utility; }
    void g( const ClientA &a ) { a.f(*utility_); }
};
class ClientC {
```
const UtilityBaseFactory *utilityFactory_;
UtilityBase *utility_;
bool shareUtility_;

public:
ClientC( const UtilityBaseFactory *utilityFactory, bool shareUtility )
:utilityFactory_(utilityFactory)
 ,utility_(utilityFactory->createUtility())
 ,shareUtility_(shareUtility) {}
~ClientC() { delete utilityFactory_; delete utility_; }

void h( ClientB *b ) {
    if( shareUtility_ ) b->initialize(utility_);
    else b->initialize(utilityFactory_->createUtility());
}

};

// Main program
int main( int argc, char* argv[] )
{
    // Read options from the commandline
    bool useA, shareUtility;
    example_get_args(argc,argv,&useA,&shareUtility);
    // Create factory
    UtilityBaseFactory *utilityFactory = 0;
    if(useA) utilityFactory = new UtilityAFactory();
    else utilityFactory = new UtilityBFactory();
    // Create cleints
    ClientA a;
    ClientB b1, b2;
    ClientC c(utilityFactory,shareUtility);
    // Do some stuff
    c.h(&b1);
    c.h(&b2);
    b1.g(a);
    b2.g(a);
    // Cleanup memory
    delete utilityFactory;
}
Listing: Refactored example C++ program using RefCountPtr<>

```cpp
#include "Teuchos_RefCountPtr.hpp"
#include "example_get_args.hpp"

// Inject symbols for RefCountPtr so we don’t need Teuchos:: qualification
using Teuchos::RefCountPtr;
using Teuchos::rcp;

// Abstract interfaces
class UtilityBase { 
    public:
        virtual void f() const = 0;
    }

class UtilityBaseFactory { 
    public:
        virtual RefCountPtr<UtilityBase> createUtility() const = 0;
    }

// Concrete implementations
class UtilityA : public UtilityBase { 
    public:
        void f() const { std::cout("UtilityA::f() called, this=\"\"\n"; } 
    }

class UtilityB : public UtilityBase { 
    public:
        void f() const { std::cout("UtilityB::f() called, this=\"\"\n"; } 
    }

class UtilityAFactory : public UtilityBaseFactory { 
    public:
        RefCountPtr<UtilityBase> createUtility() const { return rcp(new UtilityA()); } 
    }

class UtilityBFactory : public UtilityBaseFactory { 
    public:
        RefCountPtr<UtilityBase> createUtility() const { return rcp(new UtilityB()); } 
    }

// Client classes
class ClientA { 
    public:
        void f( const UtilityBase &utility ) const { utility.f(); } 
    }

class ClientB { 
    RefCountPtr<UtilityBase> utility_; 
    public:
        void initialize(const RefCountPtr<UtilityBase> &utility) { utility_=utility; } 
        void g( const ClientA &a ) { a.f(*utility_); }
```

31
class ClientC {
  RefCountPtr<UtilityBaseFactory> utilityFactory_;  
  RefCountPtr<UtilityBase> utility_; 
  bool shareUtility_; 
public:
  ClientC( const RefCountPtr<UtilityBaseFactory> &utilityFactory, bool shareUtility )
  :utilityFactory_(utilityFactory),
  ,utility_(utilityFactory->createUtility())
  ,shareUtility_(shareUtility) {}
