I. INTRODUCTION

The 5 Kwe Reactor TE System reactor is controlled by the axial movement of two control sectors in the reflector assembly. An actuator, mounted near the shield, supplies the rotational energy required to position each control sector. Environmental and performance requirements, and space allocation for the actuator are specified in Reference 1 through 11, and are summarized in Section IV.

This report describes the approach used in arriving at an optimized actuator design, and describes the prototype actuator design.

II. OPTIMIZATION APPROACH - STEPPER MOTOR

The approach to optimization was to perform the following steps iteratively, improving the design with each evolution, making such compromises as necessary to interface the various requirements.

A. Conceptual Layout

The arrangement of parts with the various parts sized on very preliminary calculations were shown on a preliminary layout drawing.

B. Calculation of Stepper Performance

The performance of various stepper motors that would fit within the conceptual layout was calculated by use of a computer analysis model.

C. Determination of Performance Requirement

The torque requirements for slow speed stepping and rapid scram were determined as a function of actuator step size because of the

system requirement of approximately 5 mils of axial control sector movement per actuator step. The actuator speed to meet scram requirement varies with step size.

D. Evaluation

The calculated actuator performance was plotted on a common basis as the requirements and the overall evaluations were made.

E. Selection

The final design of the prototype actuator was selected on the basis of performance vs. requirement evaluation.

III. OPTIMIZATION STUDY - STEPPER MOTOR

The static torque of a reluctance stepper motor, since it is a permeance machine, is described by:

$$T = K NI^2 \frac{dP}{d\theta}$$

where (Reference 12)

T = Static torque in oz-in.

K = Constant to accommodate units used

NI = Magnetomotive force in ampere turns

$\frac{dP}{d\theta}$ = Differential permeance with angular motion

This formula is the basis of the torque formula used in the computer program in the form

$$T = K L N R (B_1^2 G_1 - B_2^2 G_2)$$

where

- T = Static torque in oz-in.
 K = Constant to accommodate units used
 L = Length of teeth in inches
 N = Number of working teeth
 R = Radius of rotor teeth at gap in inches
 B_1 = Flux density, forward torque in KL/in²
 G_1 = Air gap (rotor to stator) at forward flux density
 in inches
 B_2 = Flux density, reverse torque in KL/in²
 G_2 = Air gap (rotor to stator) at reverse flux density
 in inches

Because the value $B_2^2 \times G_2$ is very difficult to calculate analytically, experimentally adjusted data were used.

Calculations were initially made to arrive at stepper motor design with a fixed length, shell diameters, and magnetic gap. The rotor diameter and the rotor and stator teeth configurations were then calculated, in accordance with the following matrix.

<u>STEP SIZE</u>	<u>TOOTH SIZE</u>	<u>ROTOR DIA.</u>
3.462° (3 teeth/pole)	.140	2.317
	.150	2.483
	.160	2.648
	.170	2.814
	.180	2.979
2.647° (4 teeth/pole)	.115	2.489
	.120	2.597
	.125	2.706
	.130	2.814
	.135	2.922
2.143° (5 teeth/pole)	.090	2.406
	.095	2.540
	.100	2.674
	.105	2.807
	.110	2.941

(cont.)

<u>STEP SIZE</u>	<u>TOOTH SIZE</u>	<u>ROTOR DIA.</u>
1.800° (6 teeth/pole)	.075	2.387
	.080	2.546
	.085	2.706
	.090	2.865
	.095	3.024
1.368° (8 teeth/pole)	.055	2.311
	.060	2.521
	.065	2.731
	.070	2.941
1.000° (11 teeth/pole)	.045	2.578
	.050	2.865
0.738° (15 teeth/pole)	.035	2.718

The inputs to the computer model used for the calculations are:

- Trial rotor dia.
- Magnetic gap
- Core length
- Shell ID
- Shell OD
- Tooth size
- Slot Depth
- Pole width
- Pole thickness
- Wire diameter
- Conductor resistivity

and the outputs are:

- Final rotor dia.
- Teeth/pole

- Coil current
- Coil voltage
- Current density
- Static torque
- Stepping torque
- Turns/coil
- Inductance
- Flux densities in all parts
- Ampere turns in all parts

A typical computed torque output, for 5 teeth/pole, 2.143° step, is shown in Figure 1.

A replot of this curve, Figure 2, shows how, for a specific current density, the output varies with the tooth size.

The maximum stepping scam torque requirements for various actuator speed (step size) are shown in Figure 3. The scam rating curve shown is the equivalent stepping torque to compensate for torque reduction associated with output speed. The rating curve was determined on the basis of experimental data generated on the S8DR design actuators as a function of actuator speed. However, unless the scam speed is greater than 8 RPM, it is the low speed requirements that are the controlling value for optimizing the actuator design. The torque requirements are tabulated:

ACTUATOR STEP SIZE VS. TORQUE REQUIREMENTS

Teeth/Pole	8	6	5	4	3
Step-degrees	1.37	1.8	2.14	2.65	3.46
4 step sequence-degrees	5.48	7.2	8.65	10.60	13.84
Ref. movement-inch	.0054	.0054	.0054	.0054	.0054
Scram RPM	4.57	6.00	7.12	8.84	11.50

(cont.)

Step torque max oz-in.	103	76	62	49	37
Scram torque max	70	50	42	39	27

Figure 4 shows how the required torques and actuator developed torque vary with actuator speed. It appears that the largest design margins exist in the range of speed between 6 to 9 RPM. The following factors tend to favor a slower speed.

1. Lower bearing surface speed.
2. Lower gear ratio, easier to integrate into the space available.
3. Larger drive pinion to reduce rotor shaft stresses.
4. Less bearing surface travel.

On the basis of the above evaluation, the 6 teeth/pole which results in 6 RPM scram speed was selected. The other parameters were then also fixed.

IV. ACTUATOR OPERATIONAL AND DESIGN REQUIREMENTS

A. Expected Operational Torques

With the selection of the actuator design parameters resulting in a 1.8° step (6 RPM scram), the expected operational torque requirements at the actuator rotor to drive and brake the control sector under the various operational modes were determined as the function of the friction coefficient of the drive system and actuator bearings. Analyses had shown the variation of the friction coefficient to be the dominant factor in the torque requirements for a given design. The expected friction coefficient is .35 over the operational conditions, with the upper

and lower limits of .60 and .10. The calculated torque requirements are shown below:

Ground test (reactor down)

Acceleration		+ 1.0g	
Friction coefficient	. 1	. 35	. 6
Stepping torque	16.4	42.2	74.4
Scram torque	9.4	27.2	50.6
Brake holding torque	3.6	0	0

Flight

Acceleration		+ 0.1g	
Friction coefficient	. 1	. 35	. 6
Stepping torque	3.9	9.9	17.3
Scram torque	0.1	1.8	6.5
Brake holding torque	1.1	0.0	0.0

Flight

Acceleration		- 0.1g	
Friction coefficient	. 1	. 35	. 6
Stepping torque	9.9	24.9	43.9
Scram torque	0.0	3.7	15.2
Brake holding torque	3.2	0.0	0.0

Launch (reactor down)

Acceleration		+ 16.25g	
Friction coefficient	. 1	. 35	. 6
Brake holding torque	138.9	0	0

Launch (reactor up)

Acceleration		-16.25g	
Friction coefficient	. 1	. 35	. 6
Brake holding torque*	170.8	0	0

* Control Sector held by mechanical "full out" stop.

B. Actuator Design Requirements

The expected ground test, launch and flight operational environments and torque requirements were evaluated to select the design requirements listed below. The torques listed include approximately 30% design margin above the maximum expected values.

Environmental

Non operating (Launch)

Temperature	50°F - 130°F		
Pressure	Sea level to 10^{-8} Torr		
Acceleration:	<u>Axial</u>	<u>Lateral</u>	
	7.5	2.0	} any combi- nation
	1.0	1.25	
	16.25	.625	
Shock	None		
Vibration	To be determined (effects expected to be less than acceleration)		

Operational

Temperature	50°F - 800°F
Thermal Cycles	~15F/minute
Pressure	1×10^{-5} Torr max
IRRADIATION (TOTAL)	1×10^{19} NVT (.1 Mev)
	5×10^{11} RAD

Performance

Output step size	7.2° (4 pulses of 1.8° each)
Stepping torque (step/sec)	100 oz-in. minimum
Scram torque (6 RPM)	70 oz-in. minimum
Brake torque (holding)	180 oz-in. minimum
Lifetime	
Hours	44,000 minimum
Thermal cycles	50 over the temp range
Operational cycles (step or scram rate)	50,000 steps in each direction

Interface

Envelope	Approx 5.0 dia by 4.0 long
Electrical	Adaptable to hard cales
Mechanical	Integral 2.78 reduction gear

V. PROTOTYPE ACTUATOR DESIGN

The design of the prototype actuator to meet the design requirements is shown on Figure 5. The design torque values are as follows:

Stepping torque	107 oz-in.
Scram torque	80 oz-in. (at 6 RPM)
Brake torque	225 oz-in.

VI. DESIGN ANALYSIS

A. Mechanical Calculations

Mechanical loads for stress analysis were based upon the combination of the maximum axial load of 16.25g, and the maximum lateral load of 2.0g, while the brake is loaded to 180 oz-in. torsional load.

Maximum stress and design factor

	<u>Stress PSI</u>	<u>Design Factor</u>
Rotor pinion	10,680	2.75
Rotor shaft	2,134	17.74
Mounting end bell	728	53.95
Brake teeth	1,512	25.45
Brake discs	73	547
Bellows (Torsion)	26,500	5.23
Bearings	17,000	.47*
Design factor is	$\frac{\text{Yield Stress}}{\text{Load Stress}}$	-1

*Identical to S8DR - all other values better than S8DR

Material capabilities for design factor calculations are as follows:

	<u>Yield Stress Ambient</u>	<u>Yield Stress 800F</u>
Hiperco 27	40,000	30,000
Inconel 718	165,000	155,000
Carbon Bearings Compressive	25,000	25,000

The only exception to the above stresses as worst case under the assumed g-loading is the bellows. When the bellows is compressed during the stepping sequence, the bending stresses exceed the torsional stresses occurring during launch as follows:

	<u>Stress PSI</u>	<u>Design Factor</u>
Bellows (flexing)	40,000	3.13

B. Electromagnetic Calculations

All values of electromagnetic calculations are similar to the S8DR values. The final selected current densities are identical to the S8DR current densities.

1. Stepper Motor

Equivalent static torque to meet rating

Stepping 160 oz-in. $\left[\frac{100}{.63} = 160 \right]$
