This form documents agreement among the parties listed below authorizing classification of the subject unit as rejected, closed out, interim closed out, or no action and authorizing backfill of the site, if appropriate. Final removal from the National Priorities List (NPL) of no action, interim closed-out, or closed-out sites will occur at a future date.

Description of current waste site condition:

The 128-B-3 waste site is a former burn and disposal site for the 100-B/C Area, located adjacent to the Columbia River. The selected remedy identified for the site was "remove, treat, and dispose," as documented in the *Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, Hanford Site, Benton County, Washington* (Remaining Sites ROD). The selected action for the site involved (1) remediating the site, (2) demonstrating through verification sampling that cleanup goals have been met, and (3) proposing the site for classification as interim closed out.

Basis for reclassification:

The 128-B-3 waste site has been remediated to meet the remedial action objectives specified in the Remaining Sites ROD. The results of verification sampling demonstrated that residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow zone soils (i.e., surface to 4.6 m [15 ft] deep). The results of sampling at upland areas of the site also showed that residual contaminant concentrations are protective of groundwater and the Columbia River. Evaluation of sampling results for the remediated river embankment concluded that further remedial action to remove soils contaminated slightly above soil remedial action goals for the protection of groundwater and the Columbia River would likely pose a greater risk to human health and the environment than leaving soils in place and backfilling the site. Therefore, an interim closure reclassification is supported for the 128-B-3 waste site, with imposition of institutional controls on the river embankment area to prevent activities that would mobilize residual contaminants to travel to groundwater or the river, to be maintained until the residual contamination can be evaluated in the context of a baseline risk assessment. This site does not have a deep zone and the upland portions of the site do not have residual contaminant concentrations that would warrant any institutional controls. The basis for reclassification is described in detail in the *Remaining Sites Verification Package for the 128-B-3 Burn Pit Site* (attached).

**REMAINING SITES VERIFICATION PACKAGE
FOR THE 128-B-3 BURN PIT SITE**

Attachment to Waste Site Reclassification Form 2006-058

November 2006

REMAINING SITES VERIFICATION PACKAGE FOR THE 128-B-3 BURN PIT SITE

EXECUTIVE SUMMARY

The 128-B-3 waste site, located within the 100-BC-1 Operable Unit and immediately adjacent to the Columbia River, was formerly used as a disposal site for the 100-B/C Area. The site was used for the dumping and burning of miscellaneous wastes, including office waste, paints, solvents, coal ash, and demolition debris. The selected remedy for the 128-B-3 site, as identified in the *Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, Hanford Site, Benton County, Washington* (Remaining Sites ROD) (EPA 1999) was “remove, treat, and dispose.”

Remediation of the site was performed from November 2004 to May 2006, consisting of the removal of approximately 21,000 BCM (bank cubic meters) (27,500 BCY [bank cubic yards]) of material from four former disposal pits, the river embankment, and the upland surface to disposal at the Environmental Restoration Disposal Facility. Initial remedial efforts at the upland area of the site were extended to include the river embankment following the results of geophysical investigation and focused sampling of visible debris at the embankment. Multiple chemical contaminants were detected above action levels in the in-process and waste characterization samples, including metals, hexavalent chromium, polycyclic aromatic hydrocarbons, total petroleum hydrocarbons (TPH), pesticides, and polychlorinated biphenyls.

Following site remediation, final verification sampling of remediation and waste staging pile footprints was conducted from June 2006 to August 2006. The results indicated that the waste removal action achieved compliance with the remedial action objectives established in the *Remedial Design Report/Remedial Action Work Plan for the 100 Area* (DOE-RL 2005b) and the Remaining Sites ROD (EPA 1999), except at the river embankment area. Residual concentrations of metals, TPH, and aroclor-1254 slightly exceeded soil RAGs for protection of groundwater and the Columbia River at this location. However, further remediation activities to remove trace remaining contamination are likely to inflict greater environmental damage than leaving said contamination in place. The results for the entirety of the site show that residual contaminant concentrations do not exceed cleanup levels for direct exposure (i.e., ingestion of the soil). Accordingly, an interim closure reclassification is supported for the 128-B-3 waste site, with imposition of institutional controls on the river embankment area to prevent activities that would mobilize residual contaminants to travel to groundwater or the river. Institutional controls will be maintained until such time that the results of a baseline risk assessment can be considered (for a final site remedy closure). The remainder of the site does not have a deep zone or residual contaminant concentrations that would require any institutional controls.

A summary of the cleanup evaluation for the soil results against the applicable criteria is presented in Table ES-1. The results of the verification sampling are used to make

reclassification decisions for the 128-B-3 waste site in accordance with the TPA-MP-14 (DOE-RL 1998) procedure.

Soil cleanup levels were established in the Remaining Sites ROD (EPA 1999) based on a limited ecological risk assessment. Although not required by the Remaining Sites ROD, a comparison against ecological risk screening levels was made for the site contaminants of concern, contaminants of potential concern, and other constituents. Ecological screening levels were exceeded for barium, boron, cadmium, chromium, lead, mercury, and vanadium. Exceedance of screening values does not necessarily indicate the existence of risk to ecological receptors. Residual concentrations of cadmium and vanadium are below site background levels, and boron concentrations are consistent with those seen elsewhere at the Hanford Site (no established background value is available). All exceedances at the site will be evaluated in the context of additional lines of evidence for ecological effects following a baseline risk assessment for the river corridor portion of the Hanford Site, which includes a more complete quantitative ecological risk assessment. That baseline risk assessment will be used to support the final closeout decision for the 128-B-3 waste site.

Table ES-1. Summary of Remedial Action Goals for the 128-B-3 Waste Site. (2 Pages)

Regulatory Requirement	Remedial Action Goals	Results	Remedial Action Objectives Attained?
Direct Exposure – Radionuclides	Attain 15-mrem/yr dose rate above background over 1,000 years.	No radionuclide COCs/COPCs were identified for the 128-B-3 waste site.	N/A
Direct Exposure – Nonradionuclides	Attain individual COPC RAGs.	All individual COC/COPC concentrations are below direct exposure RAGs.	Yes
Risk Requirements – Nonradionuclides	Attain a hazard quotient of <1 for all individual noncarcinogens.	All individual hazard quotients are less than 1.	Yes
	Attain a cumulative hazard quotient of <1 for noncarcinogens.	The cumulative hazard quotient (3.3×10^{-1}) is less than 1.	
	Attain an excess cancer risk of $<1 \times 10^{-6}$ for individual carcinogens.	All individual excess cancer risk values are less than 1×10^{-6} .	
	Attain a cumulative excess cancer risk of $<1 \times 10^{-5}$ for carcinogens.	The total excess cancer risk (2.2×10^{-6}) is less than 1×10^{-5} .	

Table ES-1. Summary of Remedial Action Goals for the 128-B-3 Waste Site. (2 Pages)

Regulatory Requirement	Remedial Action Goals	Results	Remedial Action Objectives Attained?
Groundwater/River Protection – Radionuclides	Attain single-COPC groundwater and river protection RAGs.	No radionuclide COCs/COPCs were identified for the 128-B-3 waste site.	N/A
	Attain national primary drinking water standards: ^a 4 mrem/yr (beta/gamma) dose rate to target receptor/organs.		
	Meet drinking water standards for alpha emitters: the most stringent of 15 pCi/L MCL or 1/25th of the derived concentration guides from DOE Order 5400.5. ^b	No alpha-emitting radionuclide COCs/COPCs were identified for the 128-B-3 waste site.	
	Meet total uranium standard of 30 µg/L (21.2 pCi/L). ^c	Uranium was not identified as a COC/COPC for the 128-B-3 waste site.	N/A
Groundwater/River Protection – Nonradionuclides	Attain individual nonradionuclide groundwater and river cleanup requirements.	Residual concentrations of multiple metals, polychlorinated biphenyls, and chlorinated pesticides are above soil RAGs for groundwater and/or river protection in one or more site sampling areas. However, results of vertical migration modeling indicate that these constituents will not reach groundwater (and, therefore, the Columbia River) within 1,000 years, except at the river embankment area. ^d Additional material removal at the river embankment to remove trace residual contamination is not expected to provide a benefit in consideration of the risk posed to human health and the environment by additional remediation. Therefore, institutional controls will be utilized to prevent activities that would drive residual contamination to groundwater or the river until the results of a baseline risk assessment can be considered.	No

^a “National Primary Drinking Water Regulations” (40 *Code of Federal Regulations* 141).

^b *Radiation Protection of the Public and the Environment* (DOE Order 5400.5).

^c Based on the isotopic distribution of uranium in the 100 Areas, the 30 µg/L MCL corresponds to 21.2 pCi/L. Concentration-to-activity calculations are documented in *Calculation of Total Uranium Activity Corresponding to a Maximum Contaminant Level for Total Uranium of 30 Micrograms per Liter in Groundwater* (BHI 2001).

^d *100 Area Analogous Sites RESRAD Calculations* (BHI 2005).

COC = contaminant of concern

COPC = contaminant of potential concern

MCL = maximum contaminant level

N/A = not applicable

RAG = remedial action goal

REMAINING SITES VERIFICATION PACKAGE FOR THE 128-B-3 BURN PIT SITE

STATEMENT OF PROTECTIVENESS

This report demonstrates that the 128-B-3 waste site meets the objectives for interim closure as established in the *Remedial Design Report/Remedial Action Work Plan for the 100 Area* (RDR/RAWP) (DOE-RL 2005b) and the *Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, Hanford Site, Benton County, Washington* (Remaining Sites ROD) (EPA 1999). The results of verification sampling show that residual contaminant concentrations do not preclude any future uses (as bounded by the rural-residential scenario) and allow for unrestricted use of shallow zone soils (i.e., surface to 4.6 m [15 ft] deep). The results also demonstrate that residual contaminant concentrations are sufficiently protective of groundwater and the Columbia River to preclude further remedial action. Institutional controls are required to prevent activities that would mobilize residual contamination at the river embankment area until residual contaminant concentrations can be evaluated in the context of a baseline risk assessment. No institutional controls are warranted for the upland portions of the site.

Soil cleanup levels were established in the Remaining Sites ROD (EPA 1999) based on a limited ecological risk assessment. Although not required by the Remaining Sites ROD, a comparison against ecological risk screening levels has been made for the site contaminants of concern (COCs), contaminants of potential concern (COPCs), and other constituents. Ecological screening levels were exceeded for barium, boron, cadmium, chromium, lead, mercury, and vanadium. Exceedance of screening values does not necessarily indicate the existence of risk to ecological receptors. Residual concentrations of cadmium and vanadium are below site background levels, and boron concentrations are consistent with those seen elsewhere at the Hanford Site (no established background value is available). All exceedances at the site will be evaluated in the context of additional lines of evidence for ecological effects following a baseline risk assessment for the river corridor portion of the Hanford Site, which includes a more complete quantitative ecological risk assessment. That baseline risk assessment will be used to support the final closeout decision for the 128-B-3 waste site.

GENERAL SITE INFORMATION AND BACKGROUND

The 128-B-3 waste site, part of the 100-BC-1 Operable Unit, is a former disposal site for the 100-B/C Area. The site is located in the northeastern portion of the 100-B/C Area, immediately adjacent to the Columbia River (Figure 1). The operational history of the 128-B-3 waste site is poorly documented, but assumed to be coincident with 100-B/C Area operations from 1943 to 1968. The site was used for the disposal of combustible and noncombustible wastes, including office waste, paints, solvents, coal ash, and demolition debris (DOE-RL 1994). The selected remedy for the 128-B-3 burn pit site was “remove, treat, and dispose,” as documented in the Remaining Sites ROD (EPA 1999).

Figure 1. Location of the 128-B-3 Waste Site.

REMEDIAL ACTION SUMMARY

Initial remediation of the 128-B-3 waste site was performed in November 2004, consisting of excavation of four former disposal pits and general surface material removal in the area around the disposal pits. During remedial efforts, a previously unknown prehistoric cultural site, consisting of a shell midden with stone tools, was discovered in the vicinity of one of the former disposal pits. Further remediation of the waste site was performed so as to preclude further impact to this resource. Approximately 8,810 BCM (bank cubic meters) (11,520 BCY [bank cubic yards]) of soil and debris was removed from the site surface and disposal pits and staged onsite before disposal at the Environmental Restoration Disposal Facility (ERDF). Waste staging included special segregation piles for lead, tar, and asbestos materials, as well as general waste staging piles.

A geophysical survey was performed at the site in February 2005, following initial site remediation (WCH 2006e). Data were collected using electromagnetic induction and magnetometry to identify potential residual subsurface debris. Anomalies detected in the site area above the riverbank were determined to result primarily from the large basalt boulders present at the site. No indications of any large concentrations of subsurface debris were observed in this area. Significant geophysical anomalies were detected along the riverbank area, partially attributable to surficial material, but also indicative of subsurface foreign material.

In-process samples collected from stained soils and debris at the river embankment adjacent to the initial remediation footprint (as described below) indicated the presence of hazardous constituents at levels exceeding remedial action goals (RAGs), and the scope of the remedial effort was extended to include this embankment area. Remediation along the river embankment was performed from October to November 2005, with approximately 8,700 BCM (11,380 BCY) of material excavated and disposed ERDF.

Following completion of Calendar Year 2005 remedial activities, statistical sampling was performed at the river embankment and disposal pits to ascertain if remedial action goals had been met (as described below). Sample results indicated residual concentrations of site COCs at concentrations exceeding cleanup criteria. Accordingly, approximately 3,500 BCM (4,600 BCY) of additional material was removed from these areas in April and May 2006.

A pre-excavation topographic survey of the 128-B-3 site is shown in Figure 2. Figure 3 shows the post-excavation survey for the upland area, as well as the boundaries of remedial efforts at the river embankment and the footprints of waste staging piles. Photographs of the site prior to and following remediation are provided in Appendix A.

In-process samples of soil and waste materials were collected during site remediation as needed to support waste characterization and evaluation of the waste profile for disposal of excavated material and to guide remediation efforts. Samples were collected from ash material scattered across the site (J01YT9), suspect roofing tar (J01YV0), suspect dried paint materials (J01YV1), a cylindrical suspect battery component (J02296), a drum containing wood, rock, and glass-like tar (J10LY7), a drum containing suspect oil (J10LY8), yellow-green-stained, fine-grained

Figure 2. Pre-Excavation Topographic Survey of the 128-B-3 Waste Site.

Figure 3. Post-Excavation Civil Survey of the 128-B-3 Waste Site.

soil (J02027), and other stained/discolored soils (J02289 and J10DW8). The analytical results for these samples are provided in Appendix B (Table B-1).

River Embankment Assessment

Following remediation of the four upland disposal pits, six focused sample locations were identified along the river embankment during discussion with the U.S. Environmental Protection Agency (EPA). Samples were collected on March 1, 2005, to determine if remediation of the embankment area was necessary. A summary of the samples collected, and laboratory analyses performed, is provided in Table 1.

Table 1. In-Process Sample Summary for the River Embankment at the 128-B-3 Waste Site.

Sample Location	Sample Number	Depth	Sample Analysis
Area of burned glass and metallic debris	J02J09	Surface	ICP metals (total), ICP metals (TCLP), mercury, TPH, herbicides, pesticides, and SVOA
	J02J09-A		Hexavalent chromium
Soil within exposed 0.61-m (24-in.) carbon-steel pipe segment	J02J10	Surface	ICP metals (total), ICP metals (TCLP), mercury, TPH, herbicides, pesticides, and SVOA
	J02J10-A		Hexavalent chromium
Soil beneath exposed chicken wire	J02J11	Surface	ICP metals (total), ICP metals (TCLP), mercury, TPH, herbicides, pesticides, and SVOA
	J02J11-A		Hexavalent chromium
Suspect asphalt within corroded barrel	J02J12	Surface	ICP metals (total), ICP metals (TCLP), mercury, TPH, herbicides, pesticides, and SVOA
	J02J12-A		Hexavalent chromium
Area of stressed vegetation with metallic and suspect asphaltic debris	J02J13	Surface	ICP metals (total), ICP metals (TCLP), mercury, TPH, herbicides, pesticides, and SVOA
	J02J13-A		Hexavalent chromium
Area with burned metal, glass, and rubber debris	J02J14	Surface	ICP metals (total), ICP metals (TCLP), mercury, TPH, herbicides, pesticides, and SVOA
	J02J14-A		Hexavalent chromium

Source: *100 BC Burial Grounds/Remaining Sites Sampling*, Logbook EFL-1173-4 (WCH 2006a).

ICP = inductively coupled plasma

SVOA = semivolatile organic analysis

TCLP = toxicity characteristic leaching procedure

TPH = total petroleum hydrocarbons

All samples were analyzed at offsite commercial laboratories and the results compared against the cleanup criteria specified in the *Remedial Design Report/Remedial Action Work Plan for the 100 Area* (DOE-RL 2005b). The laboratory results for all samples are provided in Appendix B (Table B-1).

Total petroleum hydrocarbons (TPH), multiple metals, and multiple pesticides were detected above soil RAGs for the protection of groundwater and/or the Columbia River in the samples.

Based on these results, it was determined that remedial activities should be extended to include the river embankment. Details of remediation performed are provided in the remedial action summary above.

In-Process Statistical Sampling (Phase I Verification Sampling)

Following Calendar Year 2005 remedial activities, Phase I verification sampling was performed within the excavated disposal pits and river embankment area at the 128-B-3 waste site to make an initial evaluation of the attainment of remedial action objectives. These areas were delineated in Visual Sample Plan¹ (VSP) and a total of 20 sample locations (see Table 2 and Figure 4) were selected based on random-start systematic grids. Additional details concerning the use of VSP to develop the statistical sampling designs are provided in the 128-B-3 waste site verification sampling work instruction (WCH 2006f).

^a A field duplicate sample was collected at sample location A-1.

N/A = not applicable

¹ Visual Sample Plan is a site map-based user-interface program that may be downloaded at <http://dgo.pnl.gov>.

Figure 4. 128-B-3 Phase I Verification Sampling Locations.

All Phase I verification samples that were collected, except for the field equipment blank, were analyzed for inductively coupled plasma (ICP) metals, mercury, hexavalent chromium, TPH, chlorinated pesticides, polychlorinated biphenyls (PCBs), and semivolatile organic compounds (SVOCs). The field equipment blank was analyzed for ICP metals, mercury, and SVOCs. Complete analytical results are provided in Appendix B.

Residual concentrations of chromium, copper, lead, mercury, zinc, multiple pesticides, and multiple polycyclic aromatic hydrocarbons in the remediated disposal pits failed one or more parts of the WAC 173-340-740(7)(e) three-part test in comparison to soil RAGs for groundwater and/or river protection. The residual concentration of aroclor-1254 in one soil sample from the disposal pits also exceeded the direct exposure RAG.

Residual concentrations of arsenic, chromium, copper, nickel, lead, manganese, silver, zinc, aroclor-1254, and TPH at the remediated river embankment failed one or more parts of the WAC 173-340-740(7)(e) three-part test in comparison to soil RAGs for groundwater and/or river protection. Residual concentrations of arsenic and lead also failed one or more parts of the three-part test in comparison to direct exposure RAGs.

Based on these results, it was determined that additional remediation was required at the 128-B-3 site, as described in the remedial action summary above.

VERIFICATION SAMPLING ACTIVITIES

Phase II verification sampling at the 128-B-3 waste site was performed from June to August 2006, to collect data to make a decision whether the remedial action objectives had been reached. Based on statistical evaluation of the resulting data, the residual contaminant concentrations meet the cleanup criteria specified in the RDR/RAWP (DOE-RL 2005b) and the Remaining Sites ROD (EPA 1999). The following subsections provide additional discussion of the information used to develop the verification sampling design. The results of verification sampling are also summarized to support interim closure of the site.

Verification Sample Design

Civil surveys and design boundaries were used to divide the 128-B-3 waste site into seven sampling areas for the purpose of verification sampling, as identified in Table 3 and shown in Figure 5. A statistical sampling design approach was implemented for Sampling Areas 1 through 4, as described below. The sampling designs for Sampling Areas 5 through 7 were based on professional judgment in consideration of conditions particular to these sampling areas and are also described below.

Figure 5. Sampling Areas and Phase II Statistical Sampling Locations at the 128-B-3 Burn Pit Site.

Table 3. 128-B-3 Sampling Areas for Phase II Verification Sampling.

Statistical Sampling Design	Judgmental Sampling Design
1) Four excavated disposal pits	5) Footprint of lead waste staging pile
2) River embankment area	6) Footprint of asbestos waste staging pile
3) Upland site surface	7) Footprint of tar staging pile
4) Footprint of general waste staging piles	

Statistical sampling was performed for the 128-B-3 remediation footprints and general waste staging piles because the spatial distribution of potential residual soil contamination over the study areas was uncertain. The decision rule for demonstrating compliance with the cleanup criteria requires comparison of the true population mean of COCs/COPCs, as estimated by the 95% upper confidence limit on the sample mean, with the cleanup level. The Washington State Department of Ecology publication *Guidance on Sampling and Data Analysis Methods* (Ecology 1995) recommends that systematic sampling with sample locations distributed over the entire study area be used. Therefore, sampling locations were distributed over the entirety of each sampling area on a unit-by-unit basis using random-start systematic grids in an effort to determine the residual presence of contamination.

VSP was used as a tool to develop the statistical sampling design for the 128-B-3 waste site. The sampling areas (Figure 5) were delineated in VSP and used as the basis for location of systematic grids for verification soil sample collection. Ten soil sample locations were identified for each of Sampling Areas 1, 2, and 4; and 17 sample locations were identified for Sampling Area 3 using random-start triangular grids. Additional details concerning the use of VSP to develop the statistical sampling design are provided in the 128-B-3 waste site verification sampling work instruction (WCH 2006f).

Figure 5 provides a map of the 47 statistical soil sample locations that were identified for verification sampling, with coordinates shown in Table 4. The soil sample locations were surveyed and staked prior to sample collection (WCH 2006c, 2006d). All sampling was performed in accordance with ENV-1, *Environmental Monitoring and Management*, to fulfill the requirements of the SAP (DOE-RL 2005a). One soil sample was collected at each location by collecting 30 aliquots of surficial soils from within approximately 1 m (3 ft) of the staked location and combining the aliquots into one sample. Field quality control (QC) samples consisted of three field duplicate samples and one equipment blank; field duplicate sample locations are identified in Table 4. All samples were requested for full protocol laboratory analysis.

Verification sampling at the special waste (lead, tar, and asbestos) staging pile footprints was based on professional judgment rather than statistical sampling designs because there was virtually no potential for contaminant migration into soils underlying the former staging piles (WCH 2006c). Sampling at each special waste staging pile footprint consisted of one sample composed of 30 aliquots of surficial soils collected from locations distributed across the entire staging footprint.

^a PCB analysis was inadvertently excluded from the analyses initially requested for samples from the upland area and general waste staging piles footprint. Therefore, additional samples were collected and submitted for PCB analysis.

^b A field duplicate sample was collected at this location.

N/A = not applicable PCB = polychlorinated biphenyl SDG = sample delivery group

Contaminants of Concern and Contaminants of Potential Concern

The COCs and COPCs for verification sampling were determined in consideration of in-process and waste characterization sampling results and the COCs/COPCs identified for similar burn pit waste sites. Residual concentrations of metals (including hexavalent chromium), SVOCs, chlorinated pesticides, TPH, PCBs, and asbestos within the remediation and general waste staging footprints were evaluated for site closure. The COCs/COPCs for the tar waste staging pile footprint were the same as for the remediation footprint, but COCs/COPCs at the lead and asbestos waste staging pile footprints were restricted to metals and asbestos, respectively.

The process history for the 128-B-3 site does not suggest the presence of radiological contamination, and radiological activity was not detected by field screening during site remediation. Therefore, radionuclides are not considered COPCs for the 128-B-3 site.

Volatile organic compounds (VOCs) were not considered site COPCs, pending field measurements with an organic vapor monitor during sampling events (WCH 2006c). However, field-screening was not performed at the time of sampling, and volatile organic analysis was requested for all sampling areas except the lead and asbestos special waste staging areas.

Based on the results of Phase I verification sampling, hexavalent chromium and TPH were removed from further evaluation under Phase II verification sampling for the excavated disposal pits, and SVOCs and pesticides were removed from further evaluation at the river embankment area.

The laboratory analyses performed for Phase II verification sampling at each sampling area are identified in Table 5.

Verification Sampling Results

Verification samples were analyzed using U.S. EPA-approved analytical methods. The 95% upper confidence limits (UCLs) on the true population means for residual concentrations of COCs and COPCs were calculated for sampling areas where statistical sampling was performed as specified by the RDR/RAWP (DOE-RL 2005b), with calculations provided in Appendix C. When a nonradionuclide COC or COPC was detected in fewer than 50% of the verification samples collected for each sampling area, the maximum detected value was used for comparison against RAGs, with the exception of TPH within the upland sampling area. If no detections for a given COC/COPC were reported in a given data set, then no statistical evaluation or calculations were performed for that COC/COPC for the associated sampling area. Evaluation of the verification data from the special waste staging pile footprints was performed by direct comparison of the maximum sample results for each COC/COPC against cleanup criteria for each sampling area.

Table 5. Analyses Performed on Phase II Verification Samples for Site Contaminants of Concern and Contaminants of Potential Concern.

^a Evaluated during Phase I verification sampling.

EPA = U.S. Environmental Protection Agency

ICP = inductively coupled plasma

NIOSH = National Institute for Occupational Safety and Health

PCB = polychlorinated biphenyl

SVOA = semivolatile organic analysis

TPH = total petroleum hydrocarbons

VOA = volatile organic analysis

The bulk parameter TPH was quantified at a maximum concentration of 258 mg/kg, slightly above the WAC 173-340-740 Method A soil remedial action goal for protection of groundwater (200 mg/kg) in one sample from the upland area verification data set. This parameter was not detected (i.e., was censored) in the remaining 94% of the sample data set, and, as described above, the statistical value is typically set equal to the maximum detected concentration under this scenario. However, doing so is a stringent test for compliance with a cleanup level, particularly since the maximum does not violate the compliance criteria of exceeding twice the cleanup level (WAC 173-340-740[7][e]). Handling censored data sets is problematic in calculating the 95% UCL, and both the Washington Department of Ecology and the EPA provide alternative guidance. For the 128-B-3 upland area, the 95% UCL value for TPH was calculated using a method suggested in *Calculating Upper Confidence Limits for Exposure Point Concentrations at Hazardous Waste Sites* (EPA 2002), in which the censored data is set equal to the quantitation limit and the 95% UCL is calculated and reported as a value likely to be considerably higher than the true mean.

Comparisons of the statistical and maximum results for COCs and COPCs and the site RAGs for all sampling areas are summarized in Tables 6a through 6f. Contaminants that were not detected by laboratory analysis are excluded from these tables. Calculated cleanup levels for aluminum, calcium, iron, magnesium, potassium, silicon, and sodium are not presented in the RDR/RAWP (DOE-RL 2005b). Parameters to calculate cleanup levels under WAC 173-340 (1996) are not available from the *Cleanup Levels and Risk Calculations (CLARC) Database* (Ecology 2005) or other reference databases. These analytes are also essential nutrients and can be eliminated from evaluation as human health concerns per EPA guidance (EPA 1989). Therefore, these constituents are not considered COPCs and are not included in the tables. All asbestos analysis results were reported as no asbestos detected or less than 1% total asbestos. The laboratory-reported data results for all constituents are stored in the Environmental Restoration (ENRE) project-specific database prior to being provided to the Hanford Environmental Information System (HEIS) and are presented within the statistical calculations in Appendix C.

DATA EVALUATION

Residual concentrations of the following were determined to exceed soil RAGs for the protection of groundwater and/or the Columbia River at the 128-B-3 waste site:

- Aroclor-1254 within the disposal pit excavations (Table 6a)
- Aroclor-1254, 4,4'-DDE, and 4,4'-DDT at the upland area (Table 6c)
- Copper, lead, mercury, zinc, aroclor-1254, aroclor-1260, 4,4'-DDE, 4,4'-DDT, and dieldrin within the general waste staging pile footprint (Table 6d)
- Barium, lead, aroclor-1254, and aroclor-1260 within the tar waste staging pile footprint (Table 6e)
- Barium and lead within the lead waste staging pile footprint (Table 6f).

Based on the K_d (soil-partitioning or distribution coefficient) values for these constituents (>22 mL/g), none are expected to migrate further than 3 m (10 ft) vertically in 1,000 years (BHI 2005). The vadose zone underlying the base of the disposal pit excavations is approximately 9-m (30-ft)-thick, and thicker underlying the surface areas of the site; therefore, residual concentrations of these contaminants are protective of groundwater. The only pathway for contaminants to reach the Columbia River is via groundwater migration, so these contaminant concentrations are also protective of the river.

Residual concentrations of total chromium, copper, lead, zinc, and TPH within the site remediation footprint along the river embankment slightly exceeded soil RAGs for the protection of groundwater and/or the Columbia River (Table 6b). Protectiveness cannot be demonstrated using vertical migration modeling for these constituents within this sampling area, due to the immediate proximity of groundwater and the Columbia River. However, the detected concentrations of these constituents are low and further remediation activities to remove trace remaining contamination are likely to inflict greater environmental damage than leaving said contamination in place. Therefore, institutional controls will be used to prevent activities at the river embankment area that would mobilize residual contaminants to travel to groundwater or the river. This restriction will be maintained until a final remedy or closure determination can be made, in consideration of the results of the river corridor baseline risk assessment.

When using a statistical sampling approach, a RAG requirement for nonradionuclides is the WAC 173-340-740(7)(e) three-part test. The application of the three-part test for the 128-B-3 waste site sampling areas where statistical sampling was performed is included in the site-specific statistical calculations (Appendix C). The three-part test is not applicable to the special waste staging pile footprint results since direct evaluation of the maximum detected sampling results was used as the compliance basis. All residual COC/COPC concentrations for the 128-B-3 site pass the three-part test in comparison to direct exposure RAGs. In addition to the exceedances addressed above, residual barium and aroclor-1254 concentrations within the river embankment remediation footprint (Table 6b), residual copper concentrations at the upland area (Table 6c), and residual barium concentrations within the general waste-staging piles' footprint (Table 6d) fail the three-part test in comparison to soil RAGs for the protection of groundwater and/or the Columbia River.

As above, neither copper ($K_d = 22$ mL/g) nor barium ($K_d = 25$ mL/g) at the upland area and general waste-staging piles' footprint is predicted to migrate more than 3 m (10 ft) vertically in 1,000 years, as compared to a vadose zone thickness in excess of 9 m (30 ft) beneath the site surface. Therefore, residual concentrations of these metals within these sampling areas are also protective of groundwater and the Columbia River. As above, protectiveness of groundwater and the Columbia River cannot be demonstrated for barium and aroclor-1254 at the river embankment remediation footprint using vertical migration modeling. However, individual detections were only slightly above the statistical background level for barium and the limits of analytical quantitation for aroclor-1254. Again, further remediation to remove these trace residual contaminant levels is not likely to provide additional benefits in consideration of the risk posed to the river and riparian environment posed by potential releases associated with such remediation.

Nonradionuclide risk requirements include an individual hazard quotient of less than 1.0, a cumulative hazard quotient of less than 1.0, an individual contaminant carcinogenic risk of less than 1×10^{-6} , and a cumulative carcinogenic risk of less than 1×10^{-5} . For the 128-B-3 waste site, these risk values were conservatively calculated for the entire site using the highest of the determined concentrations (as summarized in Tables 6a through 6f) for each constituent. These risk values were not calculated for constituents that were either not detected or were detected at concentrations below Hanford Site or Washington State background values. All individual hazard quotients were less than 1.0, and all individual excess carcinogenic risk values were less than 1×10^{-6} (Appendix D). The cumulative hazard quotient for those noncarcinogenic constituents above background or detection levels is 3.3×10^{-1} , and the cumulative excess carcinogenic risk value for these constituents is 2.2×10^{-6} . Therefore, nonradionuclide risk requirements are met.

DATA QUALITY ASSESSMENT

A data quality assessment (DQA) was performed to compare the confirmatory sampling approach and resulting analytical data with the sampling and data requirements specified in the site-specific work instruction (WCH 2006f). This DQA was performed in accordance with site specific data quality objectives found in the SAP (DOE-RL 2005a).

A review of the work instruction (WCH 2006f), the field logbooks (WCH 2006c, 2006d), and applicable analytical data packages has been performed as part of this DQA. All samples were collected per the sample design. To ensure quality data, the SAP data assurance requirements and the data validation procedures for chemical and radiochemical analysis (BHI 2000a, 2000b) were used, as appropriate. This review involves evaluation of the data to determine if they are of the right type, quality, and quantity to support the intended use (i.e., closeout decisions). The DQA completes the data life cycle (i.e., planning, implementation, and assessment) that was initiated by the data quality objectives process (EPA 2000).

Data from Phase II verification samples collected at the 128-B-3 Burn Pit site were provided by the laboratories in sample delivery groups SDGs K0464, K0465, K0475, K0476, K0482, K0530, K0531, 06I-3367-01, 06I-3442-01, 06I-3446-01, and 06I-3471-01. SDG K0465 was submitted for third-party validation. Two major deficiencies are identified in the data for SDGs K0464 and K0482, below. No major deficiencies were identified in the remaining data, all of which is acceptable for decision-making purposes. Major and minor deficiencies, as well as third-party validation qualifiers are discussed by SDG below. The 128-B-3 Burn Pit site was administratively divided into sampling areas; samples from several sampling areas may be included in any one SDG. A cross-reference for samples and SDGs is provided in Table 4.

SDG K0464

This SDG consists of 19 field samples (J12PX4 through J12PX9, J12PY0 through J12PY8, and J12P49 through J12P52). These field samples were analyzed for VOCs, SVOCs, pesticides, ICP metals, mercury, and hexavalent chromium. The work instruction (WCH 2006f) also identified PCB analysis as a requirement for these samples. Because these samples were inadvertently not

analyzed for PCBs, new samples were collected from the same locations and analyzed for PCBs in SDGs K0530 and K0531. A major deficiency was found in SDG K0464. Deficiencies in SDG K0464 are as follows:

In the volatile organic analysis (VOA), 4 of 70 matrix spike/matrix spike duplicate (MS/MSD) recoveries were outside of the acceptance criteria range. The MSDs for cis-1,3-dichloropropane and trans-1,3-dichloropropane were both below the acceptance criteria at 59%. This suggests a low bias for these two analytes and the data is considered estimated but useable for decision-making purposes. The MS and MSD for acetone were above the acceptance criteria at 219% and 193%, respectively. Acetone is considered estimated with a high bias. High-biased data are acceptable for decision-making purposes.

The common laboratory contaminant methylene chloride was found in the VOA method blank (MB) (0.002 mg/kg), and in all of the field samples (0.010 to 0.027 mg/kg). All of these detections are below the required detection limit (RDL) and the lowest RAG. The data are useable for decision-making purposes.

In the semivolatile organic analysis (SVOA), 1 of 128 MS recoveries was below the acceptance criteria. The MS for 2,4-dinitrophenol was below the acceptance criteria range at 1% recovery. The MSD and LCS recoveries for 2,4-dinitrophenol were within the acceptance criteria range. The laboratory cites "erratic chromatographic behavior" as the cause of this deficiency. The project has qualified the 2,4-dinitrophenol data in SDG K0464 as rejected with an "R" flag on the data because of the low matrix spike recovery. The 2,4-dinitrophenol data in SDG K0464 are not useable for decision-making purposes. It should be noted that this analyte has been rejected on a technical basis. There were no associated analytes detected in the samples, such as the related mononitrophenols: 2-nitrophenol and 4-nitrophenol. Solvents such as this are not typically found individually without other detections. There are no known Hanford Site processes that would have resulted exclusively in this analyte. Therefore, there is no reason to assume that 2,4-dinitrophenol was present in the samples.

In the pesticide analysis, 14 of 46 surrogate recoveries, distributed among 11 samples exceeded the laboratory acceptance criteria range (80 to 120%). All of these recoveries were in the range of 120 to 130%, within the project acceptance criteria (70 to 130%). These results suggest a slight high bias in some of the pesticide data. High-biased data are acceptable for decision-making purposes.

One of the continuing calibration verification (CCV) samples in the pesticide analysis was out of criteria. The pesticide analysis is conducted using two analytical columns to confirm detections. Chromatography from the alternate column was used to quantify the samples, such that the sample data are unaffected by this deficiency. The data are useable for decision-making purposes.

In the pesticide analysis, the analyte toxaphene was not included in the MS, MSD, or LCS samples. Toxaphene is actually a mixture of compounds, rather than a discrete analyte. The overall concentration of toxaphene can be calculated using several unobstructed peaks in the chromatography; the inclusion of toxaphene in the spiking mixture would be problematic for the

other pesticide analytes. The laboratory typically quantitates toxaphene but does not include toxaphene in QA(quality assurance)/QC samples. The toxaphene data is, therefore, considered estimated but useable for decision-making purposes.

In the metals analysis, MS recoveries for four analytes (aluminum, iron, antimony, silicon) were outside of acceptance criteria. For these analytes, the spiking concentration was insignificant compared to the concentration in the sample from which the MS was prepared. This deficiency in the MS recovery is more a reflection of the analytical variability, relative to the native sample concentrations, rather than a measure of the spike recovery from the sample. To confirm quantitation, post-digestion spikes (PDSs) and serial dilutions were prepared and analyzed for the four analytes with acceptable results (99.1 to 103.3%). The data are useable for decision-making purposes.

The relative percent difference (RPD) for boron in the laboratory duplicate was above the acceptance criteria (30%) at 31.6%. This result is attributed to difficulty in producing truly homogeneous mixtures in environmental soil samples. The lack of homogenous soil samples often results in enhanced RPDs. It is likely that more essentially inert material (e.g., larger size gravel) was present in one sample. The boron results may be considered estimated, but are useable for decision-making purposes.

SDG K0465

This SDG consists of nine field samples (J12P53 through J12P55, J12PW9, J12PY9, and J12PX0 through J12PX3). These field samples were analyzed for VOCs, SVOCs, pesticides, TPH, hexavalent chromium, ICP metals, and mercury. The work instruction (WCH 2006f) also identified PCB analysis as a requirement for these samples. Because these samples were inadvertently not analyzed for PCBs, new samples were collected from the same locations and analyzed for PCBs in SDGs K0530 and K0531. No major deficiencies were found in SDG K0465. The SDG was also submitted for third-party validation. Minor deficiencies and third-party data qualifiers are as follows:

In the VOA, the common laboratory contaminant methylene chloride was found in the MB and all of the field samples at concentrations less than the RDL. The field sample concentrations are in the range of 0.009 to 0.022 mg/kg and the MB concentration is 0.002 mg/kg. Third-party validation qualified all of the methylene chloride results in SDG K0465 (except for samples J12P53 and J12PY9) as nondetected with "U" flags. The methylene chloride concentration in sample J12P53 was raised to the RDL and qualified as non-detected with a "U" flag. No qualification was added to the methylene chloride result for sample J12PY9. The data are useable for decision-making purposes.

The MS/MSD samples in the VOA analysis were analyzed slightly outside of the tune time established for the analytical equipment (a mass spectrophotometer). The analysis was not repeated because, by the time the discrepancy was identified, the samples were out of hold time. The two MSs had good agreement and the surrogate and analyte recoveries were within criteria. There is no impact on the field sample results. The data are useable for decision-making purposes.

Three RPDs in the VOA laboratory duplicate analysis were above the acceptance criteria. Elevated RPDs are attributed to natural heterogeneities in the sample matrix. Third-party validation qualified all of the acetone, 2-butanone, and 2-hexanone results in SDG K0465 as estimated with "J" flags. The data are useable for decision-making purposes.

In the SVOA, the common laboratory contaminant bis(2-ethylhexyl)phthalate was detected in the MB below the RDL at 0.020 mg/kg.; bis(2-Ethylhexyl)phthalate was also detected in the field samples in the range of 0.017 to 0.100 mg/kg. Third-party validation raised the bis(2-ethylhexyl)phthalate results to the RDL in all of the samples and qualified them all as non-detected with "U" flags. The data are useable for decision-making purposes.

Two of the pesticide surrogate recoveries in sample J12P55 were above the acceptance criteria at 120% and 128%. This suggests a high bias in the J12P55 pesticide data for the associated analytes. Third-party validation qualified the detected analytes that are associated with the elevated surrogates as estimated with "J" flags. This qualification was limited to the endrin aldehyde result for sample J12P55. The data are useable for decision-making purposes.

In the pesticide analysis, the analyte toxaphene was not included in the MS, MSD, or LCS samples. The laboratory typically quantitates toxaphene but does not include toxaphene in QA/QC samples. Third-party validation qualified all of the toxaphene data as estimated with "J" flags. The toxaphene data is useable for decision-making purposes.

The laboratory reported an RPD for hexavalent chromium of 66.2%. The hexavalent chromium results in the main sample and the laboratory duplicate were reported as 0.25 mg/kg and 0.20 mg/kg U, respectively. Because hexavalent chromium was non-detected in 1 of the 2 samples (the laboratory duplicate), the meaning of an RPD calculation is unclear and the calculation is not usually performed. Calculated RPDs for data near the detection limit are usually elevated because of expected increased analytical variability near the detection limit. No qualification has been added. The data are useable for decision-making purposes.

In the ICP metals analysis, the MS for antimony was below the acceptance criteria range at 49.8%. Third-party validation qualified all of the antimony data in SDG K0465 as estimated with "J" flags. The data are useable for decision-making purposes.

Four other analytes (aluminum, iron, manganese, silicon) in the ICP metals analysis had MS results that were outside the acceptance criteria range. For these analytes, the spiking concentration was insignificant compared to the concentration in the sample from which the MS was prepared. This deficiency in the MS recoveries is more of a reflection of the analytical variability relative to the sample concentration than a measure of the recovery of the spike from the sample. To confirm quantitation, PDSs and serial dilutions were prepared and analyzed for the four analytes with acceptable results (96.7 to 101.9%). No qualifications were added due to these results. The data are useable for decision-making purposes.

The ICP metals LCS result for silicon was below the acceptance criteria range at 53.8%. Third-party validation qualified all of the silicon data in SDG K0465 as estimated with "J" flags. The data are useable for decision-making purposes.

SDG K0475

This SDG consists of 19 field samples (J12P05 through J12P24). Because of variable sample needs in different sampling areas, the individual samples were submitted for some or all of the following analyses: VOA, SVOA, pesticides, TPH, hexavalent chromium, ICP metals, mercury, and PCBs. Please refer to Table 4 for a detailed account of the sampling areas, associated sample numbers, and applicable analyses. No major deficiencies were found in SDG K0476. The minor deficiencies are as follows:

The common laboratory contaminant methylene chloroide was found in the VOA MBs (0.003 to 0.005 mg/kg) and in the field samples (0.004 to 0.011 mg/kg) at values less than the RDL. Based on the MB results, these detections are all small enough that methylene chloride can be considered non-detected in the field samples. The data are useable for decision-making purposes.

In the SVOA, 1 of 128 MS recoveries is below the acceptance criteria. The MS recovery for 1,2,4-trichlorobenzene is 58%. This result suggests a low bias in the 1,2,4-trichlorobenzene data. The 1,2,4-trichlorobenzene data are considered estimated but useable for decision-making purposes.

In the SVOA, 2 of 64 LCS recoveries are below the acceptance criteria. The LCS recoveries for 1,2,4-trichlorobenzene and 2-methylnaphthalene are 53% and 59%, respectively. These results suggest a low bias in the data for these analytes. The 1,2,4-trichlorobenzene and 2-methylnaphthalene data are considered estimated but useable for decision-making purposes.

The common laboratory contaminants bis(2-ethylhexyl)phthalate and di-n-butylphthalate were found in the SVOA MB and all of the field samples at concentrations below the RDLs. The data for these two analytes are considered estimated but useable for decision-making purposes.

In the pesticide analysis, 2 of 30 surrogates were below the acceptance criteria. Surrogate recoveries in sample J12P09 were 26% and 28%. There is a 5-fold difference between the practical quantitation limit and the limit of quantitation. Therefore, analytes in the pesticide analysis would still have been detected at the RDL, if they had been present in sample J12P09. The non-detected pesticide analytes (all analytes) in sample J12P09 are considered estimated but useable for decision-making purposes.

In the TPH analysis, an LCS recovery was above the laboratory acceptance criteria (120%) at 120.4 %. This result suggests a slight high bias in the TPH analysis for SDG K0475. The TPH data are considered estimated but useable for decision-making purposes.

In the ICP metals analysis, the LCS recovery for silicon was below the acceptance criteria at 26.2%. Silicon often exhibits low recovery in the LCS, which suggests a low bias in the data for silicon. The silicon data are considered estimated but useable for decision-making purposes.

Four analytes (aluminum, iron, antimony, silicon) in the ICP metals analysis had MS results outside the acceptance criteria range. Analyte concentrations from the spiking mixture are often insignificant compared to the native concentrations found in the sample from which the MS was prepared. This deficiency in the MS recoveries is more of a reflection of the analytical variability relative to the sample concentration than a measure of the recovery of the spike from the sample. To confirm quantitation, PDSs and serial dilutions were prepared and analyzed for the four analytes with acceptable results (97 to 104%). The data are useable for decision-making purposes.

The RPD calculated from the ICP metals laboratory duplicate for copper was above the acceptance criteria at 55.8%. Elevated RPDs are attributed to natural heterogeneities in the sample matrix due to well known problems in producing homogeneous soil samples from environmental matrices. The copper data are considered estimated but useable for decision-making purposes.

SDG K4076

This SDG consists of four field samples (J12P25, J12P26, J12P56, and J12P57). Because of variable sample needs in the different sampling areas, the individual samples were submitted for some or all of the following analyses: VOA, SVOA, pesticides, TPH, hexavalent chromium, ICP metals, mercury, and PCBs. Please refer to Table 4 for a detailed account of the sampling areas, associated sample number, and applicable analyses. No major deficiencies were found in SDG K0476. Minor deficiencies are as follows:

The common laboratory contaminant methylene chloride was found in the VOA MB at a concentration less than the RDL. There is no significant impact on the field sample data. The data are useable for decision-making purposes.

The VOA MS result for 1,1,2,2-tetrachloroethane did not meet the acceptance criteria at 135%. This result suggests a high bias in the 1,1,2,2-tetrachloroethane data. High-biased data are considered estimated but useable for decision-making purposes.

In the VOA, 3 of 70 LCS recoveries were below the acceptance criteria (cis- and trans-1,3-dichloropropane, both at 67%, and 1,1,2,2- tetrachloroethane at 64%). These results suggest a slight low bias in the data for these analytes. The data are considered estimated but useable for decision-making purposes.

The VOA MSD, but not the MS, was analyzed past hold time. The overall hold time was less than twice the prescribed hold time. The field samples were analyzed within hold time. The MSD data are considered estimated, but there is no impact on the field sample data. The data are useable for decision-making purposes.

The common laboratory contaminant bis(2-ethylhexyl)phthalate was found in the SVOA MB at a concentration less than the RDL. There is no significant impact on the field sample data. The data are useable for decision-making purposes.

In the SVOC analysis, 11 of 128 MS recoveries were outside of the acceptance criteria. The analytes and MS recoveries were: bis(2-chloroethyl)ether 38%, 2-chlorophenol 40%, 1,3-dichlorobenzene 26%, 1,4-dichlorobenzene 27%, 1,2-dichlorobenzene 31%, 2-methylphenol 54%, 2,2-oxybis(1-chloropropane) 40%, hexachloroethane 27%, nitrobenzene 44%, 2-nitrophenol 48%, and 1,2,4-trichlorobenzene 41%. The loss of these more volatile analytes in the SVOA suggests a laboratory error during the concentration step of the extraction. The MSD and LCS recoveries are not affected. The field sample data for these analytes may have a low bias and are considered estimated but useable for decision-making purposes.

In the pesticide analysis, a CCV sample exceeded +/- 15% calibration verification on the secondary (confirmatory) column. Quantitation of the samples was performed using data from the primary column. There is no impact on the sample data. The data are useable for decision-making purposes.

In the pesticide analysis, the analyte toxaphene was not included in the MS, MSD, or LCS samples. The laboratory typically quantitates toxaphene but does not include toxaphene in QA/QC samples. The toxaphene data is, therefore, considered estimated but useable for decision-making purposes.

The MS recovery for hexavalent chromium is below the acceptance criteria at 60.2%. The low MS recovery also resulted in an elevated RPD for hexavalent chromium between the MS and the MSD, which does not have a low recovery. The LCS recovery is within acceptance criteria. These findings may suggest a low bias in the data. The hexavalent chromium data are considered estimated but useable for decision-making purposes.

In the ICP metals analysis, 7 analytes (aluminum, cadmium, chromium, iron, lead, antimony, and silicon) in the MS were recovered outside the acceptance criteria. Because sample material is used to make up the MSs and the composition of the sample matrix is not known ahead of time, the added spike can be inappropriate in relation to concentrations of an analyte in the sample. To verify quantitation, PDSs and serial dilutions were prepared from the MSs and analyzed to the analytes mentioned above. The PDSs for these analytes were all within the range of 95 to 107%. The data are considered useable for decision-making purposes.

In the ICP metals analysis, the analytes calcium and lead had elevated RPDs in the laboratory duplicate at 38.2% and 55.1%, respectively. Samples J12P25 and J12P27 are field duplicates which have elevated RPDs for the analytes copper and lead at 71% and 57%, respectively. Difficulty in producing truly homogeneous mixtures of soils is well known. Elevated RPDs such as these are attributed to natural heterogeneities in the sample matrices that make up the samples. The data are useable for decision-making purposes.

The ICP metals LCS result for silicon was below the acceptance criteria at 53.8%. This is a typical result for silicon and may suggest a low bias in the associated data. The silicon data is considered estimated but useable for decision-making purposes.

SDG K0482

This SDG consists of one field sample (J12P27), analyzed for VOCs, TPH, hexavalent chromium, ICP metals, mercury, and PCBs. One major deficiency was found in SDG K0482. Major and minor deficiencies are as follows:

The common laboratory contaminant methylene chloroide was found in the VOA MB at a concentration below the RDL. This detection is small enough that there is no appreciable impact on the methylene chloride data in the field sample. The data are useable for decision-making purposes.

The MS/MSD pair in the VOA was analyzed outside of the established hold time. The field samples were analyzed within the appropriate hold time. Because the MS/MSD pair was analyzed at less than twice the hold time, the resulting data are considered estimated but useable for decision-making purposes.

In the VOA analysis, 1 of 70 MS recoveries was below the acceptance criteria. The MS recovery for 2-hexanone was 7%. This is below the established 10% threshold for estimated data and associated 2-hexanone was therefore rejected by the project. The 2-hexanone data in SDG K0482 is not useable for decision-making purposes. It should be noted that this analyte has been rejected on a technical basis. There were no associated analytes detected in the sample and solvents such as this are not usually found individually without other detections. There are no known Hanford Site processes that would have resulted exclusively in this analyte. Therefore, there is no reason to assume that 2-hexanone was present in the sample.

SDG K0530

This SDG consists of 15 field samples (J13553 through J13567) analyzed for PCBs. Samples in previously collected SDGs were inadvertently not analyzed for PCBs as indicated in the work instruction. The original samples could not be analyzed for PCBs because the discrepancy was discovered too late to meet holding time requirements. These samples were collected from the same locations as the original samples and analyzed for PCBs within the holding time. Please refer to Table 4 for a summary of the associated samples and sample locations. No deficiencies were found in the SDG K0530 data. The data are useable for decision-making purposes.

SDG K0531

This SDG consists of 14 field samples (J13568 through J13581) analyzed for PCBs. Samples in previously collected SDGs were inadvertently not analyzed for PCBs as indicated in the work instruction. The original samples could not be analyzed for PCBs because the discrepancy was discovered too late to meet holding time requirements. These samples were collected from the same locations as the original samples and analyzed for PCBs within the holding time. Please

refer to Table 4 for a summary of the associated samples and sample locations. No deficiencies were found in the SDG K0531 data. The data are useable for decision-making purposes.

SDG 06I-3367-01

This SDG consists of 20 field samples (J12P58 through J12P77) analyzed for asbestos. No deficiencies were found in the SDG 06I-3367-01 data. The data are useable for decision-making purposes.

SDG 06I-3442-01

This SDG consists of one field sample (J12P78) analyzed for asbestos. No deficiencies were found in the SDG 06I-3442-01 data. The data are useable for decision-making purposes.

SDG 06I-3446-01

This SDG consists of seven field samples (J12P79 through J12P85) analyzed for asbestos. No deficiencies were found in the SDG 06I-3446-01 data. The data are useable for decision-making purposes.

SDG 06I-3471-01

This SDG consists of 24 field samples (J12P86 through J12P99, J12PB0 through J12PB6, and J12R21 through J12R23) analyzed for asbestos. No deficiencies were found in the SDG 06I-3471-01 data. The data are useable for decision-making purposes.

Summary

Limited, random, or sample matrix-specific influenced batch QC issues such as those identified above are a potential for any analysis. The number and types seen in these data sets were within expectations for the matrix types and analyses performed. The DQA review of the 128-B-3 verification sampling data found that, with the exception of two instances of data being rejected (see SDG K0464 and SDG K0482), the results are accurate within the standard errors associated with the analytical methods, sampling, and sample handling. The DQA review for 128-B-3 waste site concludes that the reviewed data are of the right type, quality, and quantity to support the intended use. Detection limits, precision, accuracy, and sampling data group completeness were assessed to determine if any analytical results should be rejected as a result of QA and QC deficiencies. Except for the two exceptions mentioned above, the analytical data were found acceptable for decision-making purposes. The verification sample analytical data are stored in the ENRE project-specific database prior to being submitted for inclusion in the HEIS database. The verification sample analytical data are also provided with the statistical calculations in Appendix C.

SUMMARY FOR INTERIM CLOSURE

The 128-B-3 waste site has been remediated in accordance with the Remaining Sites ROD (EPA 1999) and the RDR/RAWP (DOE-RL 2005b). The site was remediated by removing approximately 21,000 BCM (27,500 BCY) of material to disposal at ERDF. Statistical and judgmental sampling to verify the completeness of remediation was performed, and analytical results for upland areas were shown to meet the cleanup objectives for direct exposure, groundwater protection, and river protection. Analytical results for the remediated river embankment were shown to meet the cleanup objectives for direct exposure and to not significantly exceed soil RAGs for protection of groundwater and the Columbia River. This evaluation concluded that further remedial action to remove additional soils would likely pose a greater risk to human health and the environment than leaving soils in place and backfilling the site. Accordingly, an interim closure reclassification is supported for the 128-B-3 waste site, with imposition of institutional controls on the river embankment area to prevent activities that would mobilize residual contaminants to travel to groundwater or the river. Institutional controls will be maintained until such time that the results of a baseline risk assessment can be considered (for a final site remedy or closure). The remainder of the site does not have a deep zone or residual contaminant concentrations that would require any institutional controls.

ENDNOTES

- ^a Lookup values and RAGs obtained from the RDR/RAWP (DOE-RL 2005b) or calculated per WAC 173-340-720, 730, and 740, Method B, 1996, unless otherwise noted.
- ^b Noncarcinogenic cleanup level calculated from WAC 173-340-740(3), 1996 (Method B for soils) (as presented in the 100 Area RDR/RAWP [DOE-RL 2005b]). Updated oral reference dose values (as provided in the Integrated Risk Information System [IRIS]) yield Method B direct exposure RAG values of 16,000 mg/kg and 120,000 mg/kg for barium and chromium, respectively.
- ^c Barium soil cleanup level for groundwater protection calculated from WAC 173-340-740(3)(a)(ii)(A), 1996 ("100 times rule") and WAC 173-340-720(3), 1996 (Method B for groundwater) is 112 mg/kg (as presented in the RDR/RAWP [DOE-RL 2005b]). The updated oral reference dose value (as provided in IRIS) yields a Method B groundwater cleanup criteria of 7 mg/L, as compared to the more restrictive maximum contaminant level (MCL) of 2 mg/L (40 CFR 141). Per WAC 173-340-740(3)(a)(ii)(A), 1996 ("100 times rule"), the most restrictive updated soil cleanup level for groundwater protection would be 200 mg/kg.
- ^d Where cleanup levels are less than background, cleanup levels default to background (WAC 173-340-700[4][d]) (1996).
- ^e Barium soil cleanup level for river protection calculated from WAC 173-340-740(3)(a)(ii)(A), 1996 ("100 times rule"), a dilution-attenuation factor of 2, and WAC 173-340-720(3), 1996 (Method B for groundwater) is 224 mg/kg (as presented in the RDR/RAWP [DOE-RL 2005b]). No surface water bioconcentration factor is available for barium and no ambient water quality criteria (AWQC) value exists separate from the previous drinking water standard; therefore no WAC 173-340-730(3), 1996 (Method B for surface waters) value can be determined.
- ^f Carcinogenic cleanup level calculated based on the inhalation exposure pathway per WAC 173-340-750[3], 1996 (Method B for air quality) and an airborne particulate mass loading rate of 0.0001 g/m³ (WDOH 1997).
- ^g No Hanford Site-specific or Washington State background value available.
- ^h No parameters are available from the Ecology Cleanup Levels and Risk Calculations database (Ecology 2005), and no bioconcentration factor or AWQC values are available to calculate cleanup levels (WAC 173-340-730(3)(a)(iii), 1996 [Method B for surface waters]).
- ⁱ Analyte was not retained for evaluation under Phase II verification sampling within the sampling area; value based on quantitation in Phase I verification sampling.
- ^j Calculated cleanup level (per WAC 173-340-720(3), 1996 [Method B for groundwater] and WAC 173-340-740(3)(a)(ii)(A), 1996 ["100 times rule"]) presented is lower than that presented in the RDR/RAWP (DOE-RL 2005b), based on updated oral reference dose value (as provided in IRIS).

- ^k RAG values for TPH obtained from WAC 173-340-740(2), 1996 (Method A for soils).
- ^l Where cleanup levels are less than the RDL, cleanup levels default to the RDL (WAC 173-340-707[2], 1996 and DOE-RL 2005b).
- ^m Based on the *100 Area Analogous Sites RESRAD Calculations* (BHI 2005), Aroclor-1254 is not expected to migrate more than 1 m (3.3 ft) vertically in 1,000 years. The vadose zone underlying the disposal pits remediation footprint is approximately 9 m (30 ft) thick.
- ⁿ RAG value listed in the RDR/RAWP (DOE-RL 2005b) is based on the use of benzo(a)pyrene as a surrogate. Compound-specific carcinogenic cleanup level calculated per WAC 173-340-740(3), 1996 (Method B for soils) using Oak Ridge National Laboratory oral cancer potency factors.
- ^o The statistical verification data set fails the second and/or third component of the WAC 173-340-740(7)(e) 3-part test in comparison against soil RAGs for groundwater and/or river protection (one or more sample concentrations exceeds twice the soil RAG value and/or more than 10% of the data set exceeds the soil RAG value).
- ^p The river embankment sampling area extends to groundwater and the Columbia River; therefore, no uncontaminated zone exists to evaluate the sampling area by the *100 Area Analogous Sites RESRAD Calculations* (BHI 2005).
- ^q Hanford Site-specific background value is not available; not evaluated during background study. Value used is from *Natural Background Soil Metals Concentrations in Washington State* (Ecology 1994).
- ^r Based on the *100 Area Analogous Sites RESRAD Calculations* (BHI 2005), contaminant is not expected to migrate more than 3 m (10 ft) vertically in 1,000 years. The vadose zone underlying the upland area and waste staging pile footprints is at least 13 m (43 ft) thick.
- ^s Direct exposure and groundwater protection RAG values for chlordane were mistakenly calculated based on carcinogenicity data for lindane in the RDR/RAWP (DOE-RL 2005b). Corrected values are presented in this table.
- ^t Toxicity data for this chemical are not available. RAGs for benzo(g,h,i)perylene and phenanthrene are based on the surrogate chemicals pyrene and anthracene, respectively.

Acronyms and notes apply to all of the tables in this appendix.

B = blank contamination (organic constituents)

C = blank contamination (inorganic constituents)

D = diluted

HEIS = Hanford Environmental Information System

IC = ion chromatography

J = estimate

NA = not applicable

PQL = practical quantitation limit

Q = qualifier

TCLP = toxicity characteristic leaching procedure

U = undetected

Acronyms and notes apply to all of the tables in this appendix.

Note: Data qualified with B, C, D and/or J are considered acceptable values.

B = blank contamination (organic constituents)

C = blank contamination (inorganic constituents)

D = diluted

HEIS = Hanford Environmental Information System

J = estimated

PQL = practical quantitation limit

Q = qualifier

U = undetected

APPENDIX C

CALCULATION OF 95% UCL VALUES FOR VERIFICATION DATA

CALCULATION COVER SHEET

Project Title: 100-B/C Field Remediation **Job No.** 14655
Area 100-B/C
Discipline Environmental ***Calc. No.** 0100B-CA-V0296
Subject 128-B-3 Waste Site Phase I Verification 95% UCL Calculations
Computer Program Excel **Program No.** Excel 2003

The attached calculations have been generated to document compliance with established cleanup levels. These calculations should be used in conjunction with other relevant documents in the administrative record.

Committed Calculation ☒ Preliminary ☐ Superseded ☐ Voided ☐

Calc. No. 0100B-CA-V0296 Rev. No. 1
 Checked T. M. Blakley *TMB* Date 10/26/06
 Sheet No. 1 of 5

Summary**Purpose:**

Calculate the 95% upper confidence limit (UCL) values to evaluate compliance with cleanup standards for analytes detected during Phase I sampling and removed from consideration as contaminants of concern (COCs)/contaminants of potential concern (COPCs) for further sampling at the 128-B-3 waste site. Also, perform the *Washington Administrative Code* (WAC) 173-340-740(7)(e) 3-part test for each such constituent.

Solution:

Calculation methodology is described in Ecology Pub. #92-54 (Ecology 1992, 1993), below, and in the RDR/RAWP (DOE-RL 2005b). Use sample data to perform the 95% UCL calculation for each analyte and the WAC 173-340-740(7)(e) 3-part test. The hazard quotient and carcinogenic risk calculations are located in a separate calculation brief as an appendix to the Remaining Sites Verification Package (RSVP).

Calculation Description:

The subject calculations were performed on data from soil samples from the subject waste site. The data were entered into an EXCEL 2003 spreadsheet and calculations performed by using the built-in spreadsheet functions and/or creating formulae within the cells. The statistical evaluation of data for use in accordance with the RDR/RAWP (DOE-RL 2005b) is documented by this calculation. Duplicate RPD results are used in evaluation of data quality within the RSVP for this site.

Methodology:

For (nonradioactive) analytes with $\leq 50\%$ of the data below detection limits, the statistical value calculated to estimate the true population mean is the 95% UCL. For (nonradioactive) analytes with $> 50\%$ of the data below detection limits, the maximum detected value for the data set is used instead of the 95% UCL. No value is determined for data sets with no reported detections. No radioactive analytes were identified as COCs/COPCs for the subject site. Calculations are provided only for those analytes that were detected in at least one sample from a decision unit and were removed from further consideration as COCs/COPCs for additional sampling at that decision unit.

All (nonradionuclide) data reported as being undetected are set to $\frac{1}{2}$ the detection limit value for calculation of the statistics (Ecology 1993). No radioactive analytes were identified as COCs/COPCs for the subject site. For the statistical evaluation of duplicate sample pairs, the samples are averaged before being included in the data set, after adjustments for censored data as described above.

For nonradionuclides, the WAC 173-340 statistical guidance suggests that a test for distributional form be performed on the data and the 95% UCL calculated on the appropriate distribution using Ecology software. For nonradionuclide small data sets ($n < 10$) and all radionuclide data sets, the calculations are performed assuming nonparametric distribution, so no tests for distribution are performed. For nonradionuclide data sets of ten or greater, as for the subject site, distributional testing and calculation of the

Summary**Purpose:**

Calculate the 95% upper confidence limit (UCL) values to evaluate compliance with cleanup standards for the subject site. Also, perform the *Washington Administrative Code* (WAC) 173-340-740(7)(e) 3-part test for each nonradioactive contaminant of concern (COC) and contaminant of potential concern (COPC) and calculate the relative percent difference (RPD) for primary-duplicate sample pairs, as necessary.

Solution:

Calculation methodology is described in Ecology Pub. #92-54 (Ecology 1992, 1993), below, and in the RDR/RAWP (DOE-RL 2005b). Use data from attached worksheets to perform the 95% UCL calculation for each analyte, the WAC 173-340-740(7)(e) 3-part test for nonradionuclides, and the RPD calculations, as required. The hazard quotient and carcinogenic risk calculations are located in a separate calculation brief as an appendix to the Remaining Sites Verification Package (RSVP).

Calculation Description:

The subject calculations were performed on data from soil verification samples from the subject waste site. The data were entered into an EXCEL 2003 spreadsheet and calculations performed by using the built-in spreadsheet functions and/or creating formulae within the cells. The statistical evaluation of data for use in accordance with the RDR/RAWP (DOE-RL 2005b) is documented by this calculation. Duplicate RPD results are used in evaluation of data quality within the RSVP for this site.

Methodology:

For nonradioactive analytes with ≤50% of the data below detection limits and all detected radionuclide analytes, the statistical value calculated to evaluate the effectiveness of cleanup is the 95% UCL. For nonradioactive analytes with >50% of the data below detection limits, the maximum detected value for the data set is used instead of the 95% UCL (with the exception of total

Summary (continued)

petroleum hydrocarbons [TPH] in Sampling Area C). The 95% UCL is not calculated for data sets with no reported detections. The evaluation of the portion of each analyte's data set below detection limits was performed by direct inspection of the attached sample results, and no further calculations were performed for those data sets where >50% of the data was below detection limits (with the exception of TPH within Sampling Area C). The 95% UCL values were not calculated for aluminum, calcium, iron, magnesium, potassium, silicon, and sodium, as no cleanup values are available in Ecology (2005) under WAC 173-340-740(3), and these constituents are thus not considered site COPCs.

All nonradionuclide data reported as being undetected are set to 1/2 the detection limit value for calculation of the statistics (Ecology 1993), with the exception of TPH within Sampling Area C. In cases where third-party validation requalified detected results as nondetected due to method blank contamination, but did not change the laboratory quantitation limit (e.g., methylene chloride within Sampling Area C), 1/2 the reported value was used for calculation of the statistics. For radionuclide data, calculation of the statistics is done using the reported value. In cases where the laboratory does not report a value below the minimum detectable activity (MDA), half of the MDA is used in the calculation. For the statistical evaluation of duplicate sample pairs, the samples are averaged before being included in the data set, after adjustments for censored data as described above.

TPH was detected at a maximum concentration of 258 mg/kg in Sampling Area C, slightly above the soil remedial action goal for protection of groundwater, in one sample from the data set. TPH was not detected (i.e., was censored) in the remainder (94%) of the sample data set, and, as described previously, the statistical value is typically set equal to the maximum detected concentration under this scenario. However, doing so is a stringent test for compliance with a cleanup level, particularly since the maximum does not violate the compliance criteria of exceeding twice the cleanup level, as described below. Therefore, for Sampling Area C, the 95% UCL value for TPH was calculated using a method suggested in EPA (2002), in which the censored data is set equal to the detection limit and the 95% UCL calculated using the resulting data set.

For nonradionuclides, the WAC 173-340 statistical guidance suggests that a test for distributional form be performed on the data and the 95% UCL calculated on the appropriate distribution using Ecology software. For nonradionuclide small data sets ($n < 10$) and all radionuclide data sets, the calculations are performed assuming nonparametric distribution, so no tests for distribution are performed. For nonradionuclide data sets of ten or greater, as for the subject site, distributional testing and calculation of the 95% UCL is done using Ecology's MTCASat software (Ecology 1993). Due to differences in addressing censored data between the RDR/RAWP (DOE-RL 2005b) and MTCASat coding and due to a limitation in the MTCASat coding (no direct capability to address variable quantitation limits within a data set), substitutions for censored data are performed before software input and the resulting input set treated as uncensored.

The WAC 173-340-740(7)(e) 3-part test is performed for nonradionuclide analytes only and determines if:

- 1) the 95% UCL exceeds the most stringent cleanup limit for each COPC/COC,
- 2) greater than 10% of the raw data exceed the most stringent cleanup limit for each COPC/COC,
- 3) the maximum value of the raw data set exceeds two times the most stringent cleanup limit for each COPC/COC.

The WAC 173-340-740(7)(e) 3-part test is not performed for COPCs/COCs where the statistical value defaults to the maximum value in the data set. Instead, direct comparison of the maximum value against site RAGs (within the RSVP) is used as the compliance basis.

The RPD is calculated when both the primary value and the duplicate value for a given analyte are above detection limits and are greater than 5 times the target detection limit (TDL). The TDL is a laboratory detection limit pre-determined for each analytical method, listed in Table II-1 of the SAP (DOE-RL 2005a). Where direct evaluation of the attached sample data showed that a given analyte was not detected in the primary and duplicate sample, further evaluation of the RPD value was not performed. The RPD calculations use the following formula:

$$RPD = [|M-S| / ((M+S)/2)] * 100$$

where, M = main sample value S = split (or duplicate) sample value

For quality assurance/quality control (QA/QC) split and duplicate RPD calculations, a value less than 30% indicates the data compare favorably. For regulatory splits, a threshold of 35% is used (EPA 1994). If the RPD is greater than 30% (or 35% for regulatory split data), further investigation regarding the usability of the data is performed. As a matter of good practice, when an analyte is detected in the primary or duplicate sample, but was quantified at less than 5 times the TDL in one or both samples, an additional parameter is evaluated. In this case, if the difference between the primary and duplicate results exceeds a control limit of 2 times the TDL, further assessment regarding the usability of the data is performed. No split samples were collected for cleanup verification of the subject site. Additional discussion is provided in the data quality assessment section of the applicable RSVP, as necessary.

Summary (continued)

In addition to the statistical samples collected from the remediation footprint at the subject site, multi-aliquot samples were collected from special waste staging areas. Statistical methodology is not applicable to non-statistical sampling, and direct evaluation of detected values within this decision unit will be used as the compliance basis. These maximum detected values are presented in the results summary for use in the RSVP.

Results:

The results presented in the summary tables that follow are for use in risk analysis and the RSVP for the subject site.

Results Summary - Sample Area A

Analyte	95% UCL ^a	Maximum ^b	Units

Note: The following abbreviations apply to all Attachment 1 tables.

Note: Data qualified with B, C, D, I and/or J are considered acceptable values.

B = method blank contamination (organic constituents)

C = method blank contamination (inorganic constituents)

D = diluted (organic constituents)

I = interference on one analytical column

J = estimated

PQL = practical quantitation limit

Q = qualifier

R = rejected

U = undetected

Subject:	128-B-3 Waste Site Hazard Quotient and Carcinogenic Risk Calculations						Sheet No. 1 of 4

PURPOSE:

Provide documentation to support the calculation of the hazard quotient (HQ) and excess carcinogenic risk values for the 128-B-3 remediation verification sampling results. In accordance with the remedial action goals (RAGs) in the remedial design report/remedial action work plan (RDR/RAWP) (DOE-RL 2005), the following criteria must be met:

- 1) An HQ of <1.0 for all individual noncarcinogens
- 2) A cumulative HQ of <1.0 for noncarcinogens
- 3) An excess carcinogenic risk of <1 x 10⁻⁶ for individual carcinogens
- 4) A cumulative excess carcinogenic risk of <1 x 10⁻⁵ for carcinogens.

GIVEN/REFERENCES:

- 1) DOE-RL, 2005, *Remedial Design Report/Remedial Action Work Plan for the 100 Areas*, DOE/RL-96-17, Rev. 5, U.S. Department of Energy, Richland Operations Office, Richland, Washington.
- 2) EPA, 1994, *Guidance Manual for the Integrated Exposure Uptake Biokinetic Model for Lead in Children*, EPA/540/R-93/081, Publication No. 9285.7-15-1, U.S. Environmental Protection Agency, Washington, D.C.
- 3) WAC 173-340, "Model Toxics Control Act – Cleanup," *Washington Administrative Code*, 1996.
- 4) WCH, 2006a, *128-B-3 Waste Site Cleanup Verification 95% UCL Calculations*, Calculation No. 0100B-CA-V0294, Rev. 0, Washington Closure Hanford, Richland, Washington.
- 5) WCH, 2006b, *128-B-3 Waste Site Cleanup Phase I Verification 95% UCL Calculations*, Calculation No. 0100B-CA-V0296, Rev. 0, Washington Closure Hanford, Richland, Washington.

SOLUTION:

- 1) Calculate an HQ for each noncarcinogenic constituent detected above background and compare to the individual HQ of <1.0 (DOE-RL 2005).
- 2) Sum the HQs and compare to the cumulative HQ criterion of <1.0.
- 3) Calculate an excess carcinogenic risk value for each carcinogenic constituent detected above background and compare to the individual excess carcinogenic risk criterion of <1 x 10⁻⁶ (DOE-RL 2005).
- 4) Sum the excess carcinogenic risk values and compare to the cumulative excess carcinogenic risk criterion of <1 x 10⁻⁵.

CALCULATION SHEET

Originator:	J. M. Capron <i>JMC</i>	Date:	10/26/06	Calc. No.:	0100B-CA-V0295	Rev.:	1
Project:	100-B/C Field Remediation	Job No:	14655	Checked:	T. M. Blakley <i>TMB</i>	Date:	10/26/06
Subject:	128-B-3 Waste Site Hazard Quotient and Carcinogenic Risk Calculations					Sheet No.	2 of 4

METHODOLOGY:

Hazard quotient and carcinogenic risk calculations for the 128-B-3 waste site were conservatively performed using the highest of the statistical/maximum values from all decision units for each analyte detected above background, as calculated in WCH (2006a, 2006b). Of the contaminants of concern (COCs) and contaminants of potential concern (COPCs) for the site, boron and molybdenum require the HQ calculations because they were detected and Washington State or Hanford Site background values are not available. Barium, chromium (total), copper, lead, mercury, and zinc were included because they were quantified above the Hanford Site background value in one or more decision units. Hexavalent chromium, Aroclor-1254, Aroclor-1260, and multiple chlorinated pesticides, semivolatile organic compounds, and volatile organic compounds (as identified in Table 1) are included because they were detected in one or more decision units by laboratory analysis and cannot be attributed to natural occurrence. All other site nonradionuclide COCs and COPCs were not detected or were detected below background levels. An example of the HQ and risk calculations is presented below:

- 1) For example, the maximum value for boron is 17.5 mg/kg, divided by the noncarcinogenic RAG value of 16,000 mg/kg (calculated in accordance with the noncarcinogenic toxics effects formula in WAC 173-340-740[3]), is 1.1×10^{-3} . Comparing this value, and all other individual values, to the requirement of <1.0 , this criterion is met.
- 2) After the HQ calculations are completed for the appropriate analytes, the cumulative HQ is obtained by summing the individual values. (To avoid errors due to intermediate rounding, the individual HQ values prior to rounding are used for this calculation.) The sum of the HQ values is 3.3×10^{-1} . Comparing this value to the requirement of <1.0 , this criterion is met.
- 3) To calculate the excess carcinogenic risk, the highest determined value for each carcinogenic analyte is divided by the carcinogenic RAG value, then multiplied by 1×10^{-6} . For example, the maximum value for hexavalent chromium is ~~4.4~~ 1.3 mg/kg; divided by 2.1 mg/kg and multiplied as indicated is ~~5.262~~ 2.62×10^{-7} . Comparing this value, and all other individual values, to the requirement of $<1 \times 10^{-6}$, this criterion is met.
- 4) After these calculations are completed for the carcinogenic analytes, the cumulative excess carcinogenic risk is obtained by summing the individual values. (To avoid errors due to intermediate rounding, the individual values prior to rounding are used for this calculation.) The sum of the excess carcinogenic risk values is 2.2×10^{-6} . Comparing this value to the requirement of $<1 \times 10^{-5}$, this criterion is met.

RESULTS:

- 1) List individual noncarcinogens and corresponding HQs >1.0 : None
- 2) List the cumulative noncarcinogenic HQ >1.0 : None
- 3) List individual carcinogens and corresponding excess cancer risk $>1 \times 10^{-6}$: None
- 4) List the cumulative excess cancer risk for carcinogens $>1 \times 10^{-5}$: None.

Table 1 shows the results of the HQ and excess carcinogenic risk calculations for the 128-B-3 waste site.

Project:	100-B/C Field Remediation	Job No:	14655	Checked:	T. M. Blakley <i>TMB</i>	Date:	10/19/06
Subject:	128-B-3 Waste Site Hazard Quotient and Carcinogenic Risk Calculations					Sheet No. 4 of 4	

1 **CONCLUSION:**

2

3 This calculation demonstrates that the 128-B-3 waste site meets the requirements for hazard quotient and
4 excess carcinogenic risk as identified in the RDR/RAWP (DOE-RL 2005).
