ABSTRACT

On August 12, 2003, the Habitat Evaluation Procedure (HEP) was used to determine baseline habitat suitability on the Gamblin Lake property, an acquisition completed by the Kalispel Tribe of Indians in December 2002. Evaluation species and appropriate models include bald eagle, black-capped chickadee, mallard, muskrat, and white-tailed deer. Habitat Suitability Index (HSI) values were visually estimated and agreed upon by all HEP team members. The Gamblin Lake Project provides a total of 273.28 Habitat Units (HUs) for the species evaluated. Conifer forest habitat provides 127.92 HUs for bald eagle, black-capped chickadee, mallard, and white-tailed deer. Forested wetland habitat provides 21.06 HUs for bald eagle, black-capped chickadee, mallard, and white-tailed deer. Wet meadow provides 78.05 HUs for Canada goose and mallard. Emergent wetland habitat provides 46.25 HUs for mallard, muskrat, and Canada goose.

INTRODUCTION

The Habitat Evaluation Procedure (HEP) was developed in 1980 by the U. S. Fish and Wildlife Service (USFWS) (USFWS 1980a, USFWS 1980b). HEP is a species-habitat based approach to assess project impacts, and it is a convenient tool to document the predicted effects of proposed management actions. The Northwest Power Planning Council (NPPC), now known as the Northwest Power and Conservation Council (NPCC), endorsed the use of HEP in its Columbia River Basin Fish and Wildlife Program to evaluate wildlife benefits and impacts associated with the development and operation of the federal Columbia River Basin hydroelectric system (NPPC 1994). The Albeni Falls Interagency Work Group (Work Group) used HEP in 1987 to evaluate wildlife impacts attributed to the Albeni Falls hydroelectric facility (Martin et al. 1988).

In 1995-1996, the Work Group (Kalispel Tribe, Coeur d’Alene Tribe, Kootenai Tribe of Idaho, Idaho Department of Fish and Game, USFWS, and U. S. Army Corps of Engineers) began implementing activities to mitigate wildlife habitat losses. Implementation activities include the protection, restoration, and enhancement of wildlife habitat. In December 2002, the Kalispel Tribe purchased the Gamblin Lake property located southeast of Sandpoint, Idaho (Figures 1 and 2). The initial baseline habitat assessment was completed in August 2003. The baseline assessment describes existing ecological conditions on the property and will be used to guide future enhancement activities.

The objective of using HEP at the Gamblin Lake Project and other protected properties is to document the quality and quantity of available habitat for selected wildlife species. In this way, HEP provides information on the relative value of the same area at future points in time so that the effect of management activities on wildlife habitat can be quantified. When combined with other tools, the baseline HEP will be used to determine the most effective on-site management, restoration, and enhancement actions to increase habitat suitability for targeted species. The same process will be replicated every five years to quantitatively evaluate the effectiveness of management strategies in improving and maintaining habitat conditions while providing additional crediting to BPA for enhanced habitat values.
Figure 1. Gamblin Lake Project vicinity near Sandpoint, Idaho.

Figure 2. Gamblin Lake Project location.
METHODS

The HEP is based on the assumption that habitat for selected wildlife species can be described by a Habitat Suitability Index (HSI). This value is derived from an evaluation of the ability of key habitat components to supply the life requisites of selected wildlife species. Habitat quality, expressed as an index or HSI, measures how suitable the habitat is for a particular species when compared to optimum habitat. The HSI varies from zero to one (optimum). The value of an area to a given species of wildlife is a product of the size of the area and the quality of the area (HSI) for the species. This product is comparable to “habitat value” and is expressed as a Habitat Unit (HU). One HU is equal to a unit of area (one acre, for example), which has optimum value to the target species.

The HEP team randomly selected various sites within each cover type from which life requisite data were collected. The HEP team visually inspected habitat quality and all values were recorded in the field (Table 1).

<td>HSI value</td>
</tr>
</tbody>
</table>

The black-capped chickadee and white-tailed deer HSI values were ascertained from 4 sites. The mallard HSI was determined from 7 sites. The HEP team did not collect black-capped chickadee or mallard data in either the deciduous forest or emergent wetland habitats. In addition, bald eagle, Canada goose, and muskrat field data were omitted and not collected by the HEP team. Therefore, habitat suitability information for these species was determined with the use of aerial photography and later field verified. Habitat Suitability Index values were determined using the equations specified in the species models for bald eagle, black-capped chickadee, Canada goose, mallard, muskrat, and white-tailed deer1 (Appendix A). A total of 11 sampling sites were permanently located using a Garmin III global positioning system (Figure 3).

Habitat cover types were delineated using 1:24,000 scale 1992 U.S. Forest Service aerial photography and on-site verification (Table 2). Supplemental information was used from the

---

1 To maintain consistency within the Albeni Falls Wildlife Mitigation Program, modified species models and histograms used by the Kalispel Tribe (Merker 1993) were used at the Gamblin Lake Project.
USFWS National Wetland Inventory map. Cover type acreage was determined using Arcview 3.1 software (Table 3). The Habitat Units were calculated using the formula:

$$HU = (\text{cover type area}) \times (\text{HSI value})$$

The HEP team collected habitat data along a transect (100-foot intervals) within each cover type. Sampling transects were lengthened to achieve a 90 percent confidence level for parameter point estimates. Adequacy of habitat sampling was determined using the formula (Lapin 1980):

$$\alpha^2 \times \sigma^2$$
Where:

\[ e^2 \]

\[ \alpha = \text{critical normal value (p=0.1) from any standard statistical reference} \]

\[ \sigma = \text{standard deviation} \]

\[ e = \text{tolerable error level} \]

Shrub presence, species, and height data were collected at 2-foot intervals along the sampling transect. Percent herbaceous cover and percent herbaceous cover composed of grass were measured using a 0.5 by 1.0 meter sampling frame (Daubenmire 1959) at 50-foot intervals along the transect. Height of the herbaceous layer was measured at 5 points within the sampling frame. A Robel pole (Robel et al. 1970) was used to determine the height-density of the herbaceous layer. Visual obstruction rating (VOR) was determined by four Robel pole measurements, two parallel and two perpendicular to the transect, and taken at 50-foot intervals along the transect. Distances to water, size of water bodies, ratios of open water to emergent vegetation, and road densities were derived from a combination of field estimation and evaluation of aerial photographs and topographic maps.

To determine the suitability of mallard brood-rearing habitat adjacent to the shoreline, aerial photography was examined and field verification was conducted 100 meters from the water’s edge in the conifer forest, scrub-shrub wetland, and forested wetland habitat types. Results for mallard data in these cover types reflect site visit estimates not actual data collection.
RESULTS

The Gamblin Lake Project is comprised of four habitat types. Emergent wetland habitat (18.50 acres) provides 46.25 HUs for mallard, muskrat, and Canada goose. Approximately 45.38 acres of wet meadow provide 78.05 HUs for Canada goose and mallard. An estimated 9.33 acres contain forested wetland habitat, providing a total of 21.06 HUs for bald eagle, black-capped chickadee, mallard, and white-tailed deer. Approximately 127.92 HUs are provided by 82.79 acres of conifer forest for bald eagle, black-capped chickadee, mallard, and white-tailed deer. Table 4 summarizes the HEP results for the Gamblin Lake Project. A total of 273.28 baseline habitat units (1.75 HUs/acre) have been protected by the purchase of this property.

**DISCUSSION**

**Conifer Forest**

An estimated 58.33% of the Gamblin Lake Project is comprised of coniferous forest (82.79 acres). This habitat type provides 50.20% of the total baseline HUs available on the Project. Conifer forest provides 50.08 HUs for breeding and wintering bald eagle, the habitat suitability of which is limited by human disturbance. Black-capped chickadee habitat is moderate as is indicated by an HSI score of 0.48. Reproductive habitat suitability for chickadees is limited by the lack of snags. Currently, the conifer forest habitat provides 39.73 HUs for black-capped chickadee. The conifer forest habitat type is not currently suitable as mallard brood-rearing habitat as is indicated by an HSI of 0.20. This cover type provides a total of 5.00 HUs for mallard. White-tailed deer habitat suitability is below moderate. A total of 33.11 baseline HUs are provided for white-tailed deer.

**Forested Wetland**

A total of 9.33 acres of deciduous forested wetland habitat provides 11.74 HUs for breeding and wintering bald eagle, black-capped chickadee, mallard, and white-tailed deer. Bald eagle habitat suitability is above moderate and limited by nest/perch trees and the proximity of the wetlands to human disturbance. Black-capped chickadee habitat is moderate and limited by the lack of snags. Mallard habitat suitability is below moderate. Forested wetlands provide 4.66 HUs and 3.73 HUs for black-capped chickadee and mallard, respectively. White-tailed deer habitat suitability in this cover type is poor (HSI=0.10) and limited by the lack of palatable hydrophytic shrubs such as willow (*Salix spp.*), red-osier dogwood (*Cornus stolonifera*), and alder (*Alnus rubra*). A total of 0.93 HUs are provided for white-tailed deer.

**Wet Meadow**

Wet meadow habitat comprises 45.38 acres (29.08%) of the Gamblin Lake Project and provides a total of 78.05 HUs for Canada goose and mallard. Canada goose habitat suitability is optimum. Mallard habitat suitability is moderate and limited by nesting cover. The wet meadow provides a total of 45.38 HUs and 32.67 HUs for Canada goose and mallard, respectively.
Emergent Wetland

Approximately 18.50 acres of emergent wetland habitat provide a total of 46.25 HUs for mallard (9.25 HUs), muskrat (18.50 HUs), and Canada goose (18.50 HUs). Mallard habitat suitability is moderate and limited by the presence of permanent water. This habitat type provides optimum suitability for muskrats and Canada goose.

ACKNOWLEDGMENTS

We would like to extend our thanks to Paul Ashley and his HEP team for providing their data collection assistance and insightful ideas about habitat enhancement potential.

Appendix A

Habitat Suitability Index Models
Bald Eagle Habitat Suitability Index Model

Overview

This model recognizes that proximity to prey base, quality of prey base, quality of nesting and perching habitat, and amount of human disturbance are the most important components determining the quality of breeding and wintering bald eagle habitat.

This HSI model was taken from:

\textbf{V}_1 \quad \text{Breeding and wintering food requirements}

\textbf{Good.} Abundant prey base (ungulate carrion, fish of several species, waterfowl, small mammals) available throughout the year within three miles of potential nest/perch site.

SI value = 1.0.

\textbf{Moderate.} Moderate prey availability within three miles of potential nest/perch site. Water sometimes frozen over early in the nesting/perching period, but some ungulate carrion available during that time. Alternative food sources may be within five miles of nest or perch.

SI value = 0.8.

\textbf{Fair.} Minimal prey base within five miles of potential nest/perch site. Water frozen over late into the nesting cycle without alternative food sources.

SI value = 0.3.

\textbf{Poor.} Insufficient prey base to sustain eagles.

SI value = 0.0.

\textbf{V}_2 \quad \text{Nest/perch structure: type, form, density}

\textbf{Best.} Old growth spruce, Douglas fir, or ponderosa pine in coniferous areas; old growth cottonwood in deciduous stands; stands dense and continuous and exceeding 10 acres in size.

SI value = 1.0.

\textbf{Good.} Scattered old growth trees in stands of moderate (mature) aged trees

\textbf{V}_3 \quad \text{Distance to water body with sufficient prey availability}

\textbf{A.} \leq 1 \text{ kilometer.} \quad \text{SI value} = 1.0.

\textbf{B.} 2 \text{ kilometers.} \quad \text{SI value} = 0.9.

\textbf{C.} 3 \text{ kilometers.} \quad \text{SI value} = 0.6.

\textbf{D.} 4 \text{ kilometers.} \quad \text{SI value} = 0.2.

\textbf{E.} \geq 4.5 \text{ kilometers.} \quad \text{SI value} = 0.0.
**\( V_4 \)** Human activity level

**Good.** Natural vegetation dominates area; no permanent developments or human structures; no human activity within the area during the nesting period.

SI value = 1.0.

**Moderate.** Area of farming ground or pasture surrounds site; occasional use of area by predictable humans, such as a farmer or stockman; human activity occurs late in the eagle nesting cycle.

SI value = 0.9.

**Fair.** Dispersed recreation campsites or trails, or occasionally used boat docks within vicinity of potential nest or perch; activity occurs during brooding period only.

SI value = 0.4.

**Poor.** Developed sites, e.g. campgrounds, boat launches, etc., within vicinity of potential nest or perch; heavy human use of area during incubation period.

SI value = 0.0.

---

**Equation**

Winter food suitability index value = \( V_1 \)

Winter perch suitability index value = \( V_2 \)

Wintering bald eagle habitat suitability index value = \( [(V_1)^2 \times V_2]^{1/3} \)

Reproductive suitability index value = \( (V_2 \times V_3 \times V_4)^{1/3} \)

Breeding bald eagle habitat suitability index value is the lower of food or reproductive suitability index values.
Black-capped Chickadee Habitat Suitability Index Model

Overview

This model considers the ability of the habitat to meet the food and reproductive needs of the black-capped chickadee as an indication of the overall habitat suitability. Cover needs are assumed to be met by the food and reproductive requisites and water is assumed not to be limiting. The food component assesses vegetation conditions, and the reproduction component assesses the abundance of suitable snags.

This HSI model was modified into a histogram from:

**V₁** Percent tree canopy closure

Percent tree canopy closure is the percent of canopy closed by vertical projection of the canopy in the cover type.

**V₂** Average height of overstory trees

The average height of overstory trees is the average height from the ground of the overstory trees present in the cover type.

**V₃** Number of snags 10 – 25 cm/0.4 ha.

Number of snags 10 – 25 cm/0.4 ha. is the number of snags usable by black-capped chickadees in the cover type.

The Habitat Suitability Index value is equal to the lowest life requisite value.
Canada Goose Habitat Suitability Index Model

Overview

This model recognizes that the quality of shoreline habitat, the presence of islands, and the quality of brood-rearing habitat are the most important components determining the quality of Canada goose breeding habitat.

This model was taken from:

**V$_1$** Island nesting habitat

**Good.** Stable islands present, relatively high shoreline/area ratio; ground cover on portions of islands 4 to 16 inches high; brood habitat within 1 mile of area.

SI value between 0.8 and 1.0.

**Fair.** Stable islands present; relatively low shoreline/area ratio; or cover on islands < 4 or > 16 inches in height or brood habitat within 1 to 2 miles from area.

SI value between 0.5 and 0.7.

**Poor.** No stable islands present; or islands with limited or no cover; or brood habitat ≥ 2 miles from area.

SI value between 0.0 and 0.4.

**V$_2$** Shoreline nesting habitat

**Good.** Portions of cover within 10 meters of water; ground cover 4 to 16 inches high; adjacent wetland buffer within 50 meters of shoreline, may include sloughs of open water; brood habitat within 1 mile.

SI value = 0.5.

**Fair.** Portions of shoreline cover within 10 meters of water; ground cover 4 to 16 inches high; adjacent wetland buffer within 50 meters of shoreline (Does not include open water wetlands); or brood habitat 1 to 2 miles away.

SI value between 0.3 and 0.4.

**Poor.** No shoreline cover or shoreline cover taller than 16 inches and/or shorter than 4 inches; or wetland buffer > 50 meters to absent or brood habitat > 2 miles away.

SI value between 0.0 and 0.2.

**V$_3$** Brood rearing habitat

**Good.** Brood pasture easily accessible from main water body; foraging zones common; vegetation < 4 inches tall; average > 1 acre in size; open water wetlands are present within 1 mile of nesting habitat.

SI value between 0.7 and 1.0.

**Fair.** Less than above and/or no open water wetlands; or area is 1 to 2 mile miles from nesting habitat.

SI value between 0.4 and 0.6.

**Poor.** Little or no brooding area; or area is ≥ 2 miles from nesting habitat.

SI value between 0.0 and 0.3.

**Equation**

The Habitat Suitability Index value = 

\[
(V_1 + V_2) V_3 
\]

1/2

\(A-8\)
Mallard Habitat Suitability Index Model  
(Breeding Season Only)

Life Requisite Values

Food (V₁): Related to the area of various wetland types within a sampling area that are shallow enough for a dabbling duck to feed (<60 cm water depth is optimum) during the breeding season. Model assumes that seasonally flooded wetlands (i.e. wet meadows, etc.) provide a better food source than permanently flooded wetlands.

Reproduction (V₂): Related to the height and density of nesting cover (residual vegetation).

Cover (V₃): Related to the percent of shoreline dominated by emergent or scrub-shrub wetland vegetation. Shorelines with little or nor vegetation provide marginal escape cover for broods. Only wetlands with open water available during the brooding season should be evaluated.

Habitat Evaluation Criteria

Food (V₁): Seasonal wetlands, which produce the highest quantities of aquatic invertebrates, are preferred feeding habitat for laying mallard hens. The density of mallard pairs/hectare is assumed to be higher in seasonal rather than semi-permanent wetlands.

A – Temporarily Flooded: Surface water is present for brief periods during growing season.

   SI value = 0.3

B – Seasonally Flooded: Surface water is present for extended periods especially early in the growing season, but is absent by the end of the season in most years.

   SI value = 1.0

C – Semi-permanently Flooded: Surface water persists throughout the growing season during most years.

   SI value = 0.8

D – Permanently Flooded: Water covers the land surface throughout the year in all years. Vegetation is composed of obligate hydrophytes.

   SI value = 0.5
Reproduction ($V_2$): Mallard nesting success is the highest in cover with the greatest height-density of residual vegetation (i.e. concealed from all directions). The Robel method was used as the visual obstruction technique (height and density). Reproduction value ($V_2$) is a function of the height and density of nesting cover (residual vegetation).

Mean 100% Visual Obstruction (decimeters)

Shoreline Cover ($V_3$): Mallard broods will utilize wetlands having sparse to dense emergent or scrub-shrub vegetation. Wetlands devoid of wetland vegetation or open water are usually avoided. Marshes with shorelines bare of emergent vegetation are used less. Measure the percent of shoreline dominated by emergent and/or scrub-shrub wetland vegetation for brood rearing wetlands (>2 acres in size with some open water during brooding season):

- A – 50% to 100% of shoreline  
  SI value = 0.7 to 1.0
- B – 15% to 50% of shoreline  
  SI value = 0.4 to 0.6
- C – 0% to 15% of shoreline  
  SI value = 0.1 to 0.3

The habitat suitability index is the lowest $V_3$ value.

Suggested Measurement Techniques

Large sampling areas that are representative should be randomly selected. At least four sampling areas per area should be used. Variables $V_1$ and $V_3$ can be measured from aerial photography with field ground truthing. Variable $V_2$ should be measured in the field in upland habitat adjacent to wetlands. Specific suggestions on measurement techniques of each variable are provided below.

$V_1 = \text{Calculate area of various wetland types within each sampling area using a digitizer or dot grid or planimeter. Multiply each wetland area by its SI for a weighted value. Sum the weighted values in the sampling area and divide by the total wetland acreage for a weighted sample area SI value.}$

$V_2 = \text{Field measure height and density of residual vegetation using the visual obstruction technique (Robel pole used here). Sampling areas should be located on aerial photographs.}$
$V_3 =$ Measure the amount of shoreline vegetation for each wetland type $>2$ acres in size and with some open water during brood-rearing season from aerial photographs. Calculate SI value for each wetland based on measurements. Multiple SI value times wetland area for a weighted value. A standard for lacustrine systems (i.e. littoral zone or 100 meters from shore) will need to be established as providing brood-rearing habitat. Sum weighted values in each sampling area and divide by total wetland acreage for a sample area SI value. Some field verification of shoreline vegetation should be conducted.
Muskrat Habitat Suitability Index Model

Overview

Year-round habitat requirements of the muskrat can be fulfilled within wetland habitats that provide herbaceous vegetation and permanent surface water with minor fluctuations in water levels. Wetlands characterized by seasonal drying, an absence of emergent vegetation, or both, have less potential as year-round muskrat habitat than wetlands with permanent water and an abundance of emergent vegetation. It is assumed that food and cover are interdependent characteristics of the muskrat’s habitat and that measures of vegetative abundance and water permanence within a wetland can be aggregated to reflect habitat conditions favoring maintenance of the muskrat’s food and cover requirements. The reproductive habitat requirements of the species are assumed to be met when adequate water, food, and cover conditions are present.

This model was modified into a histogram from:

**V₁**  Percent canopy cover of emergent herbaceous vegetation

Percent canopy cover of emergent herbaceous vegetation is the percent of the water surface shaded by a vertical projection of the canopies of all emergent herbaceous vegetation, both persistent and non-persistent.

**V₂**  Percent of year with surface water present

Percent of year with surface water present is the proportion of the year in which the cover type has surface water present.

**V₈**  Percent of emergent herbaceous vegetation of preferred types

Percent of emergent herbaceous vegetation consisting of Olney bulrush, common threesquare bulrush, or cattail considering both persistent and non-persistent types.

**Equation**

The Habitat Suitability Index value is equal to the lowest life requisite value.
White-tailed Deer Habitat Suitability Index Model  
(Winter Only)

Overview

This Suitability Index curve recognizes that the most important components determining the quality of white-tailed deer winter habitat are available browse, snow depth, and security cover. It is assumed that snow depth and cover do not limit white-tailed deer in the area surrounding Lake Pend Oreille, compared to the importance of available browse. Therefore, this Suitability Index alone is used to determine white-tailed deer winter habitat quality in the area around Albeni Falls Dam.

\[ V_4 \quad \text{Percent shrub crown cover} < 1.5 \text{ m (5 ft.) in height} \]
